# CHAPTER 1

187

## Introduction

188 The Standard Model (SM)<sup>1</sup> has been remarkably successful...

---

<sup>1</sup>Here's a footnote.

## CHAPTER 2

---

# Theoretical Framework

---

(Some example introductory text for this chapter)...

### 2.1 Introduction to the Standard Model

Modern particle physics is generally interpreted in terms of the Standard Model (SM). This is a quantum field theory which encapsulates our understanding of the electromagnetic, weak, and strong interactions...

### 2.2 Electroweak Mixing and the Higgs Field

When the theory of the electroweak interaction was first developed [2, 3], the  $W$  and  $Z$  bosons were predicted to be massless (a typical mass term in the Lagrangian would violate the  $SU(2)$  symmetry). However, these were experimentally observed to have masses...

## CHAPTER 3

---

# LHC and the ATLAS Detector

---

### 3.1 The Large Hadron Collider

The Large Hadron Collider (LHC) [\[4\]](#) is...

### 3.2 The ATLAS Detector

ATLAS is a general-purpose particle detector...

#### 3.2.1 The Inner Detector

The Inner Detector serves the primary purpose of measuring the trajectories of charged particles...

##### 3.2.1.1 Pixel Detector

The Pixel detector consists of four cylindrical barrel layers and three disk-shaped endcap layers...

##### 3.2.1.2 Semiconductor Tracker

The Semiconductor Tracker uses the same basic technology as the Pixels, but the fundamental unit of silicon is a larger “strip”...

##### 3.2.1.3 Transition Radiation Tracker

The Transition Radiation Tracker is the outermost component of the ID...

Figure 3.1: General cut-away view of the ATLAS detector [5].

### 3.2.2 The Calorimeters

ATLAS includes two types of calorimeter system for measuring electromagnetic and hadronic showers. These are the Liquid Argon (LAr) calorimeters and the Tile calorimeters. Together, these cover the region with  $|\eta| < 4.9$ ...

#### 3.2.2.1 Liquid Argon Calorimeters

The Liquid Argon system consists of...

#### 3.2.2.2 Tile Calorimeters

The Tile calorimeter provides coverage for hadronic showers...

223

## CHAPTER 4

224

---

# Alignment of the ATLAS Inner Detector

---

225 In order for the subdetectors of the ID to operate at their designed precisions, it is essential that  
226 the locations of the sensors be known as precisely as possible. Differences between the expected and  
227 actual positions of a sensor can result in displaced particle hits and degrade track reconstruction  
228 quality. These misalignments can occur for any number of reasons, including but not limited to  
229 elements shifting during maintenance periods or cycles in ATLAS's magnetic field, or simply small  
230 movements during normal detector operations. Since it is not practical to physically realign hundreds  
231 of thousands of detector elements to  $\mu\text{m}$  precision by hand, an iterative track-based alignment  
232 algorithm is used to determine the physical positions and orientations of these elements [6]. The  
233 effects of misalignments and the steps taken to correct and monitor them are detailed in this chapter.

### 234 4.1 Effects of Misalignment

235 Hello world!

### 236 4.2 The Alignment Method

237 Hello world!

### 238 4.3 Momentum Bias Corrections

243 Hello world!

## CHAPTER 5

---

# Same-sign $WW$ @ $\sqrt{s} = 13$ TeV

---

### 5.0.1 Analysis Overview

### 5.1 Theoretical motivation

Hello world!

### 5.2 Data and Monte Carlo samples

This analysis uses  $36.1 \text{ fb}^{-1}$  of  $\sqrt{s} = 13$  TeV proton-proton collision data recorded by ATLAS during 2015 and 2016. The uncertainty in the combined 2015+2016 integrated luminosity is 2.1%. It is derived following a methodology similar to that detailed in Ref. [7] and using the LUCID-2 detector for the baseline luminosity measurements [8] from calibration of the luminosity scale using  $x$ - $y$  beam-separation scans.

#### 5.2.1 Monte Carlo samples

A number of Monte Carlo (MC) simulations are employed to model signal and background processes. In order to model the real collision data as closely as possible, each MC has been run through a full simulation of the ATLAS detector [9] in GEANT4 [10], and events have been reconstructed using the same algorithms as the data. The simulation reproduces as closely as possible the momentum resolutions and calorimeter responses of the detector, and also includes the effects of pileup by including soft QCD interactions using PYTHIA v8.1 [11]. The MC samples used in this analysis are detailed in this section and summarized in Table 5.1.

Process	Generator	Comments
$W^\pm W^\pm jj$ (EWK)	SHERPA v2.2.2	Signal sample
$W^\pm W^\pm jj$ (EWK)	POWHEG-BOX v2	Systematics sample
$W^\pm W^\pm jj$ (QCD)	SHERPA v2.2.2	
Diboson	SHERPA v2.2.2	Both bosons decay leptonically ( $llll$ , $lll\nu$ , $xll\nu\nu$ )
	SHERPA v2.2.1	One boson decays leptonically, the other hadronically
Triboson	SHERPA v2.1.1	
$W$ +jets	SHERPA v2.2.1	
$Z$ +jets	Madgraph5_aMC@NLO	
$V\gamma$	SHERPA v2.1.1	
$V\gamma jj$ (EWK)	SHERPA v2.2.4	
$t\bar{t}V$	Madgraph5_aMC@NLO	
$t\bar{t}$	POWHEG-BOX v2	
Single top	POWHEG-BOX v1	EWK $t$ -, $s$ -, & $Wt$ -channels

Table 5.1: Summary of MC samples used in the analysis.

263 The  $W^\pm W^\pm jj$  samples are modeled using SHERPA v2.2.2 [12, 13, 14] with the NNPDF3.0 PDF  
 264 set [15]. The EWK signal samples are generated by fixing the electroweak coupling constant to  
 265  $\mathcal{O}(\alpha_W) = 6$ , and a QCD background sample was also generated with  $\mathcal{O}(\alpha_W) = 4$ . SHERPA includes  
 266 up to one parton at next-to-leading order (NLO) and up to three at leading order (LO) in the  
 267 strong coupling constant  $\alpha_s$ . A second  $W^\pm W^\pm jj$  EWK sample is generated using POWHEG-BOX  
 268 v2 [16] with the NNPDF3.0 PDF set and at NLO accuracy. This sample is only used for systematic  
 269 studies, as POWHEG-BOX does not include resonant triboson contributions in its matrix element, which  
 270 are non-negligible at NLO [17].

271 Diboson processes ( $VV$  where  $V = W, Z$ ) are simulated with SHERPA v2.2.2 for mixed hadronic  
 272 and leptonic decays and SHERPA v2.2.1 for fully leptonic decays of the bosons. Similarly, triboson  
 273 ( $VVV$ ) and  $V\gamma$  processes are simulated using SHERPA v2.1.1 with up to one parton at NLO and up  
 274 to three at LO.  $W$ +jets processes are simulated with SHERPA2.2.1 with up to two partons at NLO  
 275 and four at LO. All the above SHERPA samples use the NNPDF3.0 PDF set and SHERPA's own parton  
 276 showering. The  $Z$ +jets events are generated with Madgraph5\_aMC@NLO [18] at LO and interfaced  
 277 with PYTHIA v8.1 for parton showering.

278  $t\bar{t}$  events are generated using POWHEG-BOX v2 with the CT10 PDF set [19].  $t\bar{t}V$  samples are  
 279 generated at NLO with Madgraph5\_aMC@NLO and the NNPDF3.0 PDF set interfaced with PYTHIA v8  
 280 for parton showering. Finally, single top events are generated with POWHEG-BOX v1 and the CT10f4  
 281 PDF set interfaced with PYTHIA6 [20] for parton showering.

### 5.3 Background estimations

Hello world!

#### 5.3.1 Reduction of $WZ$ background using custom overlap removal

The dominant source of prompt background in this analysis comes from  $WZ$  events where both bosons decay leptonically. Traditionally, the background is dealt with by imposing a veto on any event with a third lepton passing some loose identification criteria (the so-called *trilepton veto*). In the case of this analysis, if one or more leptons (in addition to the two signal leptons) passed the preselection criteria, the event would be rejected. However,  $WZ$  events can still enter the signal region if one of the leptons fails the veto selection or falls outside of the detector's acceptance.

In order to understand the sources of  $WZ$  events that are not removed by the tripleton veto, a study was performed on truth-level leptons<sup>2</sup> on  $W^\pm W^\pm jj$  and  $WZ$  MC samples. Events with three truth leptons were selected, and each was matched to its reconstruction-level partner by finding the closest  $\Delta R(\text{truth}, \text{reco})$  and  $\Delta p_{T, \text{truth}, \text{reco}}$  match. For events surviving the tripleton veto, the two signal leptons were removed, and the remaining leptons represent real leptons that failed to be selected for the veto. Between 40-50% of these leptons fell outside of the eta acceptance of the analysis (see Figure 5.1) and were unrecoverable. The second largest source of leptons failing the preselection was the overlap removal (OR). **TODO: Make sure to define overlap removal in the event selection section!** The standard OF procedure appeared to be too aggressive in removing leptons in favor of jets, causing many three lepton events to “lose” their third lepton and pass the tripleton veto. Therefore a *Custom OR* was investigated which would replace the standard OR in the preselection and allow for better  $WZ$  rejection by removing fewer third leptons.

**TODO: Mention how the extra leptons in the  $W^\pm W^\pm jj$  are background leptons since there are only 2 from the main decay**

In order to construct a “custom” OR, a new quantity is defined between a lepton ( $l$ ) and a nearby jet ( $j$ )

$$p_{T, \text{ratio}}(l, j) = \frac{p_{Tl}}{p_{Tj}} \quad (5.1)$$

which, along with  $\Delta R(l, j)$ , will allow for more third leptons to pass the preselection. The idea behind including  $p_{T, \text{ratio}}$  is to be able to preferentially remove background leptons originating from jets (i.e. those that carry a low percentage of the total jet momentum) instead of removing *any*

<sup>2</sup>Truth particles are the particles produced directly by the MC generator before being passed through the full detector simulation, at which point they are considered *reconstruction-level* (or *reco-level*) particles.

Figure 5.1: Pseudorapidity ( $\eta$ ) distributions of truth muons (top) and electrons (bottom) for Sherpa  $W^\pm W^\pm jj$  and  $WZ$  MC samples. The blue vertical lines represent the allowed  $\eta$  range for each lepton flavor. The numbers correspond to the number of raw MC events that fall within and outside of the allowed  $\eta$  range for each MC sample.

lepton near to jet. The distributions of  $p_{T,\text{ratio}}$  and the associated efficiency curves for muons and electrons can be found in Figures 5.2 and 5.4, respectively, and the distributions for  $\Delta R(\mu, j)$  for muons can be found in Figure 5.3. Since all electrons have an associated jet in the calorimeters, the  $\Delta R(e, j)$  variable is not a good quantity to use for this custom OR.

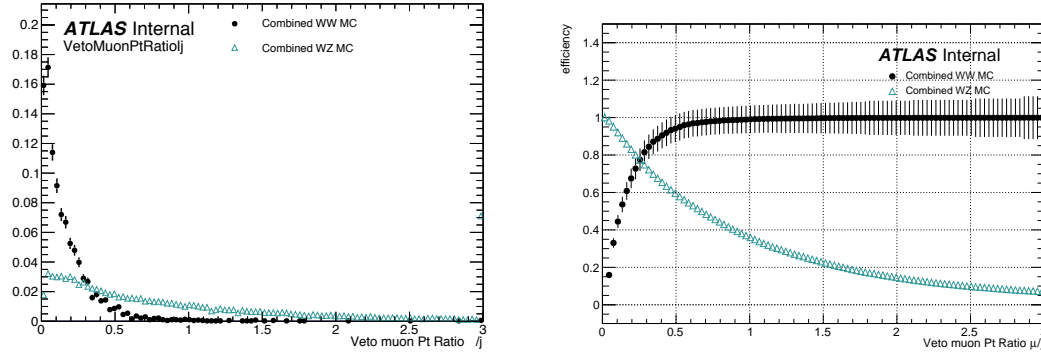

Figure 5.2: Distributions of  $p_{T,\text{ratio}}(\mu, j)$  for EWK and QCD  $W^\pm W^\pm jj$  signal (black) and  $WZ$  background (teal) for truth-matched third muons in events that pass the triplepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on  $p_{T,\text{ratio}}(\mu, j)$  at a given value on the  $x$ -axis.

A workingpoint for the Custom OR was chosen by requiring 90% signal retention for muons and 90% background rejection for electrons. The cut on electrons was allowed to be much tighter

Figure 5.3: Distributions of  $\Delta R(\mu, j)$  for EWK and QCD  $W^\pm W^\pm jj$  signal (black) and  $WZ$  background (teal) for truth-matched third muons in events that pass the tripleton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on  $\Delta R(\mu, j)$  at a given value on the  $x$ -axis.

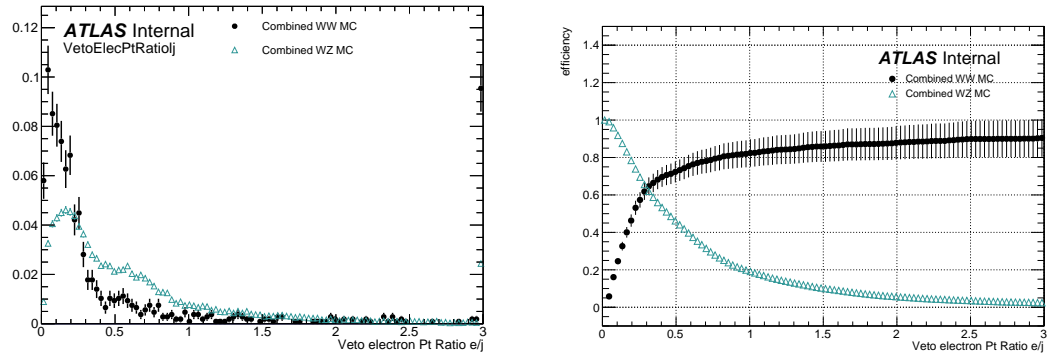

Figure 5.4: Distributions of  $p_{T,\text{ratio}}(e, j)$  for EWK and QCD  $W^\pm W^\pm jj$  signal (black) and  $WZ$  background (teal) for truth-matched third electrons in events that pass the tripleton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on  $p_{T,\text{ratio}}(e, j)$  at a given value on the  $x$ -axis.

because the number of signal events with a third electron is considerably smaller than for muons. It should be re-emphasized the signal events that are present in Figures 5.2-5.4 do not represent the full set of signal events, but only those with a real third lepton (which must come from some source other than the signal  $W^\pm W^\pm jj$  process). For muons, an or of  $p_{T,\text{ratio}}(\mu, j)$  and  $\Delta R(\mu, j)$  is used to maximize the third lepton acceptance due to correlations between the quantities, as shown in Figure 5.5; for electrons, only a cut on  $p_{T,\text{ratio}}(e, j)$  is used. The Custom OR workingpoint is outlined in Table 5.2.

Custom OR Definition	
Muons	$p_{T,\text{ratio}}(\mu, j) > 0.40$ or $\Delta R(\mu, j) > 0.15$
Electrons	$p_{T,\text{ratio}}(e, j) > 0.18$

Table 5.2: Custom OR definition. Leptons must pass this selection in order to be counted for the trilepton veto.

Figure 5.5: Two-dimensional plots of  $p_{T,\text{ratio}}(\mu, j)$  vs  $\Delta R(\mu, j)$  for truth-matched third muons in events that pass the trilepton veto for EWK and QCD  $W^\pm W^\pm jj$  signal (left) and  $WZ$  background (right). The blue overlay indicates the area in which the third leptons will pass the custom OR and result in the event failing the trilepton veto.

Tests of the performance of the Custom OR looked promising, with approximately 20% reduction in  $WZ$  background compared to less than 2% signal loss in the signal region. Unfortunately, due to differences between the primary analysis framework and the one used for testing, in practice the gains in  $WZ$  rejection were not nearly as substantial, and ultimately the Custom OR was dropped from the final analysis. However, it is still a potentially useful tool for improving background rejection via lepton number vetoes in analyses with overly aggressive OR procedures.

# Prospects for same-sign $WW$ at the High Luminosity LHC

---

On December 3, 2018, Run 2 of the LHC officially ended, and the collider was shut down to begin the first of two scheduled extended maintenance periods [21]. During these two long shutdowns, the Phase-I and Phase-II upgrades of the LHC and ATLAS will occur in order to prepare for the High-Luminosity LHC (HL-LHC) which is scheduled to begin operation in 2026 [22].

The HL-LHC is planned to run at a center-of-mass energy of  $\sqrt{s} = 14$  TeV with an instantaneous luminosity of  $\mathcal{L} = 5 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$  with up to 200 collisions per beam-crossing. Over the course of operation, the HL-LHC is expected to collect a total integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$  by 2035 [23].

These run conditions are much harsher than what ATLAS has experienced so far, and as a result there are several planned upgrades to the detector. Most notably, the entire ID will be replaced with an all-silicon tracker which will extend the coverage from  $|\eta| \leq 2.7$  up to  $|\eta| \leq 4.0$ . This will allow for reconstruction of charged particle tracks which can in turn be matched to clusters in the calorimeters for electron identification or forward jet tagging [24].

The upgraded detector combined with the higher beam energy and the considerable increase in integrated luminosity means that many analyses with low signal statistics in Run 2 have the potential to be greatly improved with the HL-LHC. While the ATLAS 13 TeV  $W^{\pm}W^{\pm}jj$  cross section measurement certainly did not suffer greatly from low statistics **TODO: -reword-**, the accuracy of the measurement can still be improved at the HL-LHC. Of particular interest is the longitudinal polarization of the  $W$  bosons due to its sensitivity to electroweak symmetry breaking [25].

The analysis detailed in this chapter is based off of the 2018 public ATLAS  $W^{\pm}W^{\pm}jj$  prospects

study [26] which is itself an extension of the 2017 ATLAS study [27]. **TODO: mention CMS's study + yellow report?**

### 6.0.1 Analysis Overview

The experimental signature of interest here is identical to the 13 TeV analysis detailed in Chapter 5: two prompt leptons (electrons or muons) with the same charge, missing transverse energy, and two jets. Once again the two leading jets are required to have a large angular separation and a high combined invariant mass to preferentially select EWK VBS production over QCD  $W^\pm W^\pm jj$  events.

Background processes that can mimic the signal are again similar to the 13 TeV analysis. The dominant source of prompt background from  $WZ$ +jets events where both bosons decay leptonically. If the lepton from the  $Z$ -decay with opposite charge from the  $W$  falls outside of the detector acceptance or is not identified, the remainder could appear to be a  $W^\pm W^\pm jj$  signal event. To a lesser extent,  $ZZ$ +jets events can enter the signal region in much the same way provided two leptons are “lost”. Other prompt sources include  $t\bar{t} + V$  and multiple parton interactions, however these processes do not contribute much. The upgrades to the ATLAS detector are expected to reduce the size of these prompt contributions due in large part to the increased detector acceptance from the forward tracking. Jets mis-reconstructed as leptons or leptons from hadronic decays (such as  $t\bar{t}$  and  $W$ +jets production) comprise the non-prompt lepton background. Lastly, events with two prompt, opposite-charge electrons can contribute provided one of the electrons is mis-reconstructed as the wrong charge.

In this analysis, the EWK production of  $W^\pm W^\pm jj$  is studied in the context of the planned HL-LHC run conditions and upgraded ATLAS detector. An optimized event selection (referred to as the *optimized selection*) is also explored in an effort to gain increased signal significance over the *default selection*. The cross section of the inclusive EWK production is measured for both the default and optimized selections, and the extraction of the longitudinal scattering significance is measured with the optimized selection.

## 6.1 Theoretical motivation

The theoretical motivation for studying the ssWW process is detailed in Section 5.1. The particular interest in polarization is the potential for the scattering amplitude of longitudinally polarized weak bosons to diverge linearly as the center of mass energy increases, ultimately violating unitarity around 1 TeV [28]. In the Standard Model, the Higgs boson cancels these divergences. However, as

the Higgs is recently discovered it is still extremely to study the mechanism of electroweak symmetry breaking (EWSB), and the longitudinal scattering of  $W$  bosons is expected to be one of the most sensitive tests of EWSB [25].

### 6.1.1 Experimental sensitivity to longitudinal polarization

There are three possible polarization states for a massive vector boson: two transverse (+ or  $-$ ) and one longitudinal (0). Therefore, in a system with two  $W$  bosons, the overall polarization can be purely longitudinal (00), purely transverse ( $++$ ,  $--$ , and  $+-$ ), or mixed ( $+0$  and  $-0$ ). The three combinations will be referred to as  $LL$ ,  $TT$ , and  $LT$  respectively.

In order to extract the longitudinal scattering component, it is necessary to find variables that distinguish the  $LL$  from the  $TT$  and  $LT$ . Several variables were studied, and those with the best discriminating power between the polarizations were the leading and subleading lepton  $p_T$  as well as the azimuthal separation ( $|\Delta\phi_{jj}|$ ) of the two VBS jets. The  $LL$  events preferred lower  $p_T$  for both signal leptons (see Figure 6.1), which motivates keeping these two cuts as low as possible in the event selection in order to preserve as much longitudinal polarization as possible. In the case of  $|\Delta\phi_{jj}|$ , the  $LL$  events generally had a larger dijet separation (see Figure 6.2), and this variable is used in a binned likelihood fit to extract the longitudinal scattering significance.

## 6.2 Monte Carlo samples

As no real HL-LHC data will be available for many years, all processes in this prospects study must be simulated using Monte Carlo (MC) generators. Signal and background processes were generated at  $\sqrt{s} = 14$  TeV, and the event yields scaled to the anticipated HL-LHC integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$ .

**TODO: Consider putting all this in a table**

The signal sample consists of both VBS and non-VBS electroweak (EWK)  $W^\pm W^\pm jj$  production, and it is simulated with the `Madgraph5_aMC@NLO` generator [18] using the `NNPDF3.0` PDF set [15] and interfaced with `PYTHIA v8` [29] for hadronization and parton showering. To study the longitudinal polarization more directly, two additional `Madgraph5_aMC@NLO`  $W^\pm W^\pm jj$  samples are used: one containing only the longitudinal contribution ( $LL$ ) and a second containing the transverse ( $TT$ ) and mixed ( $LT$ ) contributions.

There are many other processes that can produce the same final state as the  $W^\pm W^\pm jj$  and must also be accounted for using MC simulations.  $WZ$  events are generated using `SHERPA v2.2.0`

Figure 6.1: Comparison of the leading (top) and subleading (bottom) lepton  $p_T$  distributions for purely longitudinal (LL, black) and mixed polarization (LT+TT, cyan)  $W^\pm W^\pm jj$  events. Plots from [1].

Figure 6.2: Comparison of the azimuthal dijet separation ( $|\Delta\phi_{jj}|$ ) for purely longitudinal (LL, black) and mixed polarization (LT+TT, cyan)  $W^\pm W^\pm jj$  events. Plot from [1].

[12, 13, 14], which includes up to one parton at NLO in the strong coupling constant  $\alpha_s$  and up to three additional partons at LO. Both EWK and QCD production are included in these samples.  $ZZ$  and triboson  $VVV$  ( $V = W, Z$ ) events are generated using **SHERPA v2.2.2** with up to two additional partons in the final state. For the triboson backgrounds, the bosons can decay leptonically or hadronically.  $W$ +jets backgrounds are generated for electron, muon, and tau final states are generated at LO with **Madgraph5\_aMC@NLO** and the **NNPDF3.0** set with showering from **PYTHIA v8**.  $Z$ +jets events are generated using **POWHEG-BOX v2** [16] and the **CT10** PDF set [19] interfaced with **PYTHIA v8**. Finally,  $t\bar{t}$  and single-top events are generated using **POWHEG-BOX** with showering from **PYTHIA v6**.

Since the MC samples used in the analysis are generated at particle-level and have not been run through the typical full simulation of the ATLAS detector, smearing functions are instead used to estimate detector effects. These are derived from a **GEANT4** simulation of the upgraded ATLAS detector [10]. In addition, pileup events are fully simulated.

### 6.3 Background estimations

In this analysis, all background contributions are estimated using MC simulations. Backgrounds such as electron charge misidentification and fake electrons from jets—which are traditionally estimated using data-driven techniques—are estimated using a set of parameterization functions applied to the MC. These functions calculate the probability that an electron is assigned the wrong charge or a jet is mis-reconstructed as an electron parameterized by the  $p_T$  and  $\eta$  of the electron or jet. The probabilities are derived from studies on expected electron performance with the upgraded ATLAS detector [30].

Processes involving two  $W$  and  $Z$  bosons are grouped together as *diboson* backgrounds, with the exception of  $W^\pm W^\pm jj$  events produced via QCD interactions, which are kept separate. Similarly, all backgrounds with three vector bosons are combined and labeled as *triboson*. Any  $W$ +jets or top events that pass selection and do not contain a fake electron, as well as any  $Z$ +jets events without an electron identified as having its charge misidentified are combined as *other non-prompt* backgrounds.

#### 6.3.1 Truth-based isolation

Since the MC samples used in this analysis have not been run through a full detector simulation, they lack any kind of particle isolation variables (since they require, for example, information on the calorimeter response). Generally, this is not a large concern, as at truth-level, high  $p_T$  signal leptons tend to be well isolated to begin with. However, isolation is one of the most powerful tools for rejecting leptons from non-prompt sources such as top events, which are produced in association with additional nearby particles from  $b$  and  $c$  quark decays. In the absence of any sort of isolation requirement, contributions from top backgrounds (including single top,  $t\bar{t}$  and  $t\bar{t} + V$ ) were more than an order of magnitude higher than expected.

As a result, it was necessary to create an analogue to the isolation information that is available in fully-simulated samples. Track- and calorimeter-based isolation variables were constructed by summing the momentum and energy, respectively, of stable truth particles with  $p_T > 1$  GeV within a specified radius of each signal lepton. For the track-based isolation, only charged truth particles were used; both charged and neutral particles (excluding neutrinos) were included for the calorimeter-based isolation. Ultimately, a set of isolation cuts were chosen that are similar to those recommended by ATLAS for Run 2 analyses. The truth-based isolation requirements are listed in Table 6.1.

The truth-based isolation requirement reduced the top background by over 99% and reduced the contribution of top events to the total background from 83% to 2%. Additional details on the

	Electron Isolation	Muon Isolation
Track-based isolation cone size	$\Delta R < 0.2$	$\Delta R < 0.3$
Track-based isolation requirement	$\sum p_T/p_T^e < 0.06$	$\sum p_T/p_T^\mu < 0.04$
Calorimeter-based isolation cone size	$\Delta R < 0.2$	$\Delta R < 0.2$
Calorimeter-based isolation requirement	$\sum E_T/p_T^e < 0.06$	$\sum E_T/p_T^\mu < 0.15$

Table 6.1: Truth-based isolation requirements for electrons and muons.

truth-based isolation studies are presented in Appendix A.

## 6.4 Object and event selection

### 6.4.1 Object selection

Electrons and muons are preselected to have  $p_T > 7$  and 6 GeV, respectively, and  $|\eta| \leq 4.0$ . The likelihood of a given lepton to pass the trigger or identification requirements is estimated by estimating an efficiency dependent on the  $p_T$  and  $\eta$  of the lepton. The leptons are also required to pass the isolation criteria detailed in Table 6.1. Jets that have been tagged as a fake electron by the functions described earlier in Section 6.3 are treated as electrons for the purpose of the object selection and are subject to the same criteria. In order to be considered a signal lepton, an additional requirement of  $p_T > 25$  GeV is applied on top of the preselection. The two highest  $p_T$  leptons passing this selection are chosen to be the leading and subleading signal leptons.

Jets are clustered using the anti- $k_t$  algorithm [31] from final-state particles within a radius of  $\Delta R = 0.4$  (excluding muons and neutrinos). Jets are required to have  $p_T > 30$  GeV and lie within  $|\eta| < 4.5$ , with an additional cut of  $p_T > 70$  GeV for jets above  $|\eta| \geq 3.8$  in order to suppress jets from pileup interactions. Jets overlapping with a preselected electron within  $\Delta R_{e,j} < 0.05$  are removed in order to prevent double counting. The two highest  $p_T$  jets are defined as the leading and subleading *tag jets*.

### 6.4.2 Event selection

The default event selection is summarized in Table 6.2 and described here. Exactly two signal leptons are required with the same electric charge and separated from each other by 0.3 in  $\Delta R$ . In order to suppress contributions from Drell-Yan backgrounds, the two signal leptons must have an invariant mass  $m_{ll}$  greater than 20 GeV. Additionally, if both signal leptons are electrons, their mass must

be at least 10 GeV from the  $Z$ -boson mass in order to reduce background from  $Z$ -boson decays<sup>3</sup>. The event is required to have at least 40 GeV of missing transverse energy ( $E_T^{\text{miss}}$ ) to account for the two neutrinos from the  $W$  decays. Events with additional preselected leptons are vetoed, which greatly reduces  $WZ$  and  $ZZ$  backgrounds. Both tag jets are required to not overlap with the signal leptons, and there is a veto on events with one or more  $b$ -jets. In order to preferentially select VBS production, the tag jets are also required to have a large separation between them and a large invariant mass. Finally, a cut on the lepton centrality,  $\zeta$ , defined in Equation 6.1 enhances the EWK  $W^\pm W^\pm jj$  signal.

$$\zeta = \min[\min(\eta_{\ell 1}, \eta_{\ell 2}) - \min(\eta_{j 1}, \eta_{j 2}), \max(\eta_{j 1}, \eta_{j 2}) - \max(\eta_{\ell 1}, \eta_{\ell 2})] \quad (6.1)$$

Selection requirement	Selection value
Lepton kinematics	$p_T > 25 \text{ GeV}$ $ \eta  \leq 4.0$
Jet kinematics	$p_T > 30 \text{ GeV}$ for $ \eta  \leq 4.5$ $p_T > 70 \text{ GeV}$ for $ \eta  > 3.8$
Dilepton charge	Exactly two signal leptons with same charge
Dilepton separation	$\Delta R_{l,l} \geq 0.3$
Dilepton mass	$m_{ll} > 20 \text{ GeV}$
$Z$ boson veto	$ m_{ee} - m_Z  > 10 \text{ GeV}$ ( $ee$ -channel only)
$E_T^{\text{miss}}$	$E_T^{\text{miss}} > 40 \text{ GeV}$
Jet selection	At least two jets with $\Delta R_{l,j} > 0.3$
$b$ jet veto	$N_{b\text{-jet}} = 0$
Dijet separation	$\Delta\eta_{jj} > 2.5$
Trilepton veto	No additional preselected leptons
Dijet mass	$m_{jj} > 500 \text{ GeV}$
Lepton-jet centrality	$\zeta > 0$

Table 6.2: Summary of the signal event selection.

## 6.5 Selection optimization

As mentioned earlier, the HL-LHC will feature forward tracking, an increase in center of mass energy, and a higher integrated luminosity. Therefore, this study is an excellent time to see if there are new optimizations to the signal event selection that can improve the signal to background ratio.

<sup>3</sup>The electron charge mis-ID rate is high enough that contributions from  $Z \rightarrow ee$  backgrounds are non-negligible.

### 6.5.1 Random grid search algorithm

The chosen method for optimizing the event selection is a cut-based algorithm known as the Random Grid Search (RGS) [32]. Consider a simple case of two variables  $x$  and  $y$  chosen to differentiate the signal from the background. In order to be considered a signal event, a given event would be required to pass a *cut point*  $c = \{x > x_c, y > y_c\}$ . A simple method to choose the optimal cut point (i.e. the “best” values of the cuts  $x_c$  and  $y_c$ ) would be to construct an  $n \times m$  rectangular grid in  $x$  and  $y$  consisting of points  $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_m)$ , as in Figure 6.3. One can then choose a cut point  $c_k = \{x > x_i, y > y_j\}$  that maximizes the signal significance as measured by a chosen metric. This would be considered a *regular* or *rectangular* grid search.

While effective in principle, this rectangular grid search comes with two major drawbacks:

1. The algorithm does not scale well as the number of variables to be optimized—the dimensionality of the grid—increases. In the case of a square grid with  $N$  bins per variable  $v$ , the number of cut points to be evaluated grows as  $N^v$ .
2. Signal and background samples are rarely evenly distributed over the entire grid, resulting in many cut points being sub-optimal and evaluating them would be a waste of computing resources.

To combat these limitations, the RGS algorithm constructs a grid of cut points directly from the signal sample itself. In the two-dimensional example, this means that the variables  $x_i$  and  $y_j$  making up the cut point  $c_k = \{x > x_i, y > y_j\}$  take their values directly from a given signal event. This has the benefit of creating a *random grid* of cut points that is by construction biased towards regions of high signal concentration. This reduces the need for exponentially increasing numbers of cut points while ensuring that computing resources are not wasted in regions with few to no signal events. An example of the the two-dimensional random grid is shown in Figure 6.4.

Once the random grid of cut points is constructed, the optimal cut point can be chosen using whatever metric the analyzer chooses, such as signal to background ratio. For the purpose of the  $W^\pm W^\pm jj$  upgrade study, the optimal cut point is the one that maximizes the signal significance  $Z$  defined as in Equation 6.2 [33].

$$Z = \sqrt{2 \left[ (s+b) \ln \left( \frac{s+b}{b_0} \right) + b_0 - s - b \right] + \frac{(b-b_0)^2}{\sigma_b^2}} \quad (6.2)$$

Figure 6.3: A visual representation of a rectangular grid search algorithm. The signal events are the blue triangles, and the red circles are the background events. **TODO: replace with own figure**

Figure 6.4: A visual representation of a random grid search algorithm. The signal events are the blue triangles, and the red circles are the background events. **TODO: replace with own figure**

where  $s$  and  $b$  are the number of signal and background events, respectively,  $\sigma_b$  is the total uncertainty on the background, and  $b_0$  is defined as:

$$b_0 = \frac{1}{2} \left( b - \sigma_b^2 + \sqrt{(b - \sigma_b^2)^2 + 4(s + b)\sigma_b^2} \right) \quad (6.3)$$

In the case where the background is known precisely (i.e.  $\sigma_b = 0$ ), Equation 6.2 simplifies to

$$Z = \sqrt{2 \left( b \left[ (1 + s/b) \ln(1 + s/b) - s/b \right] \right)} \quad (6.4)$$

which further reduces to the familiar  $Z = s/\sqrt{b}$  for the case when  $s \ll b$ .

### 6.5.2 Inputs to the optimization

In order to train the RGS, signal and background samples were prepared from events passing the event selection outlined in Table 6.2 up through the  $b$ -jet veto. The signal sample was chosen to be the longitudinally polarized  $W^\pm W^\pm jj$  EWK events, and the transverse and mixed polarizations were treated as background along with  $W^\pm W^\pm jj$  events from QCD interactions and the traditional backgrounds listed in Section 6.3. Splitting the inclusive  $W^\pm W^\pm jj$  EWK events by polarization allows the optimization to favor the longitudinally polarized events as much as possible, even though they both contribute to the EWK signal.

The following variables were chosen for optimization:

- Leading lepton  $p_T$
- Dilepton invariant mass ( $m_{ll}$ )
- Leading and subleading jet  $p_T$
- Dijet invariant mass ( $m_{jj}$ )
- Lepton-jet centrality ( $\zeta$ )

Subleading lepton  $p_T$  was omitted as it is desirable to keep the cut value as low as possible due to its sensitivity to the longitudinal polarization (as discussed in Section 6.1.1). Additionally, the dijet separation  $\Delta\eta_{jj}$  was included in the optimization originally, however it was dropped from the list due to the cut value being motivated by differences between EWK and QCD produced  $W^\pm W^\pm jj$  events.

Two additional constraints were imposed when selecting the optimal cut point:

1. At least 1000 signal events must survive in order to prevent the optimization from being too aggressive and unnecessarily reducing signal statistics.

551 2. The dijet invariant mass may only vary within a 50 GeV range of the default value (from  
 552 450-550 GeV) due to the cut being physically motivated by the VBS event topology (**TODO:**  
 553 **reference where this is discussed in the 13TeV section** ).

554 Lastly, the decision was made to use calculate the signal significance without taking into account  
 555 the uncertainty of the background using Equation 6.4. This was due to the fact that the statistical  
 556 uncertainties of the fake electron and charge-misID backgrounds were quite large, and if Equation 6.2  
 557 were used instead, the optimization would cut unreasonably hard against these backgrounds. Since  
 558 Monte Carlo statistics is not expected to be a limiting factor when this analysis is performed at the  
 559 HL-LHC, it is more realistic to simply ignore these large statistical uncertainties for the purpose of  
 560 the selection optimization.

### 561 6.5.3 Results of the optimization

562 Ultimately, the random grid was constructed from over 38,000 LL-polarized  $W^\pm W^\pm jj$  events in  
 563 the variables listed above. After applying the constraints, an optimal cut point was chosen which  
 564 reduced the total background from 9900 to 2310 while reducing the signal from 3489 to 2958. This  
 565 corresponds to an increase in signal significance from  $Z = 33.26$  to  $Z = 52.63$  as calculated by  
 566 Equation 6.4. The updates to the event selection are listed in Table 6.3.

567 The large reduction in the background is primarily a result of the increase in the leading and  
 568 subleading jet  $p_T$  from 30 GeV to 90 GeV and 45 GeV, respectively. As can be seen in Figure 6.7,  
 569 this increase removes a significant portion of the backgrounds from jets faking electrons and charge  
 570 mis-ID. Additionally, the loosening of the lepton-jet centrality cut  $\zeta$  allows more signal events to  
 571 survive the event selection (see Figure 6.9). Other changes to the event selection are minor and do  
 572 not individually have a large impact on the signal or background yields.

573 The full event yields after optimization as well as the cross section measurement are detailed  
 574 alongside those using the default selection in Section 6.6.

575 **TODO: It's a bit awkward to reference the results of the default/optimized before they're prop-**  
 576 **erly presented. Maybe move the sections around? not sure...**

Selection requirement	Selection value
Lepton kinematics	$p_T > 28$ GeV (leading lepton only)
Jet kinematics	$p_T > 90$ GeV (leading jet) $p_T > 45$ GeV (subleading jet)
Dilepton mass	$m_{ll} > 28$ GeV
Dijet mass	$m_{jj} > 520$ GeV
Lepton-jet centrality	$\zeta > -0.5$

Table 6.3: Updates to the  $W^\pm W^\pm jj$  event selection criteria after optimization. Cuts not listed remain unchanged from the default selection in Table 6.2.

## 6.6 Results

### 6.6.1 Event yields

After applying the full event selection, the analysis is broken down into four channels based off the flavor of the signal leptons:  $\mu\mu$ ,  $ee$ ,  $\mu e$ , and  $e\mu$ . The full signal and background event yields are shown in Table 6.4 for each channel separately and combined using the default event selection. EWK  $W^\pm W^\pm jj$  events are expected compared to 9900 background events. The dominant sources of background are jets faking electrons followed by charge misidentification and diboson processes. Triboson events, QCD  $W^\pm W^\pm jj$ , and other non-prompt sources make up approximately 5% of the total background combined.

	All channels	$\mu\mu$	$ee$	$\mu e$	$e\mu$
$W^\pm W^\pm jj$ (QCD)	206.4	91.1	22.8	38.4	54.1
Charge Misidentification	2300	0.0	2100	90	160
Jets faking electrons	5000	0.0	3400	1200	340
$WZ + ZZ$	2040	500	438	423	680
Tribosons	115	47	15.4	21.6	31.2
Other non-prompt	210	110	20	60	27
Total Background	9900	750	6000	1900	1290
Signal $W^\pm W^\pm jj$ (EWK)	3489	1435	432	679	944

Table 6.4: Signal and background event yields using the default event selection for an integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . Events containing a fake or charge-flipped electron are removed from their respective sources and combined into a single entry each.

The event yields for the optimized selection detailed in Section 6.5.3 are listed in Table 6.5. After optimization, 2958 signal events and just 2310 background events are expected. Diboson events now are the primary source of background, as the optimization greatly reduces the fake and charge misidentification backgrounds. As discussed earlier, the increase in the leading and subleading jet  $p_T$  cuts as well as the loosening of the centrality cut are most responsible for the changes in the

591 signal and background yields; distributions of these quantities using the default and the optimized  
 592 event selections can be found in Figures 6.10, 6.11, and 6.12, respectively.

	All channels	$\mu\mu$	$ee$	$\mu e$	$e\mu$
$W^\pm W^\pm jj$ (QCD)	168.7	74.6	19.7	32.2	42.2

Other non-prompt	120	29	16.6	50	19
Total Background	2310	455	480	660	710
Signal $W^\pm W^\pm jj$ (EWK)	2958	1228	380	589	761

Table 6.5: Signal and background event yields using the optimized event selection for an integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . Events containing a fake or charge-flipped electron are removed from their respective sources and combined into a single entry each.

Figure 6.10:  $p_T$  distributions for the leading jet using the default (left) and optimized (right) event selections for all channels combined.

593 It is important to note, however, that the MC sample used to estimate  $Z$ +jets events suffers from  
 594 poor statistics which results in large per-event weights once scaled to  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . This sample  
 595 contributes heavily to the fake and charge misidentification backgrounds, and a handful of these  
 596 events being cut out by the optimization contributes has a large effect on the dramatic reduction  
 597 of these backgrounds. As a result, these particular optimized results are likely overly optimistic.  
 598 However, given proper MC statistics, it is still expected that the optimization will outperform the  
 599 default selection.

## 600 6.6.2 Uncertainties

Figure 6.11:  $p_T$  distributions for the subleading jet using the default (left) and optimized (right) event selections for all channels combined.

Figure 6.12:  $p_T$  distributions for lepton-jet centrality  $\zeta$  using the default (left) and optimized (right) event selections for all channels combined.

601 **TODO:** Ask for details on how some of these uncertainties were calculated – specifically the fakes and  
 602 **charge mis-ID** The uncertainties considered for the analysis are summarized in Table 6.6. Values for  
 603 experimental systematics on the trigger efficiency, lepton and jet reconstruction, and flavor tagging  
 604 are taken directly from the 13 TeV analysis **TODO: (cite or reference?)**. The rate uncertainties for  
 605 the background processes are halved from the 13 TeV values.

### 606 6.6.3 Cross section measurement

607 The cross section is calculated using the same method as in the 13 TeV analysis, detailed in Chap-  
 608 ter 5. **TODO: update from chapter reference to subsection reference (once it's written)...** Once  
 609 again, each of the four lepton flavor channels is further split by charge (i.e.  $\mu\mu \rightarrow \mu^+\mu^+ + \mu^-\mu^-$ ),

Source	Uncertainty (%)
$W^\pm W^\pm jj$ (EWK)	3
Luminosity	1
Trigger efficiency	0.5
Lepton reconstruction and identification	1.8
Jets	2.3
Flavor tagging	1.8
Jets faking electrons	20
Charge misidentification	25
$W^\pm W^\pm jj$ (QCD)	20
Top	15
Diboson	10
Triboson	15

Table 6.6: Summary of estimated experimental and rate uncertainties.

as this increases the sensitivity of the analysis. Each channel's  $m_{jj}$  distribution is combined in a profile likelihood fit to extract the EWK  $W^\pm W^\pm jj$  production cross section. The expected cross section calculated using the default event selection is:

$$\sigma_{W^\pm W^\pm jj}^{\text{expected}} = 16.89 \pm 0.36 \text{ (stat)} \pm 0.53 \text{ (theory)} \pm 0.84 \text{ (syst)} \text{ fb} \quad (6.5)$$

The expected cross section calculated using the optimized event selection is:

$$\sigma_{W^\pm W^\pm jj}^{\text{expected}} = 16.94 \pm 0.36 \text{ (stat)} \pm 0.53 \text{ (theory)} \pm 0.78 \text{ (syst)} \text{ fb} \quad (6.6)$$

The optimized selection should not change the measured value of the cross section, and indeed both are consistent within uncertainties. The systematic uncertainty is reduced by approximately 7% with the optimized selection. Projections of the total uncertainty on the cross section as a function of integrated luminosity made by **TODO: how was this made?** is shown in Figure 6.13.

#### 6.6.4 Longitudinal scattering significance

**TODO: get some details on how this was all done...** The longitudinal scattering significance is extracted from the  $|\Delta\phi_{jj}|$  distribution using a simultaneous binned likelihood fit. In order to increase sensitivity, the  $|\Delta\phi_{jj}|$  distribution was split into two bins in  $m_{jj}$ , and an additional cut on the pseudorapidity of the subleading lepton was applied ( $|\eta| < 2.5$ ) to reduce background from fake and charge misidentification. The  $|\Delta\phi_{jj}|$  distributions used in the fit are shown in Figure 6.14. Due to limited statistics, the four lepton flavor channels were not split by charge. The expected significance of the  $W_L^\pm W_L^\pm jj$  process is  $1.8\sigma$  with a precision of 47% on the measurement. Projections of the expected significance as a function of integrated luminosity is shown in Figure 6.15.

Figure 6.13: Projections of the statistical (black), theoretical (blue), systematic (yellow), and total (red) uncertainties on the measured cross section as a function of integrated luminosity using the optimized event selection.

Figure 6.14: Dijet azimuthal separation ( $|\Delta\phi_{jj}|$ ) for the low  $m_{jj}$  region ( $520 < m_{jj} < 1100$  GeV, top) and the high  $m_{jj}$  region ( $m_{jj} > 1100$  GeV, bottom). The purely longitudinal (LL, gray) is plotted separately from the mixed and transverse (LT+TT, cyan) polarizations.

Figure 6.15: Projections of the expected longitudinal scattering significance as a function of integrated luminosity when considering all sources of uncertainties (black) or only statistical uncertainties (red).

627

# CHAPTER 7

628

## Conclusion

629 Here’s where you wrap it up.

630 **Looking Ahead**

631

632 Here’s an example of how to have an “informal subsection”.

## Additional material on truth isolation
