## List of Tables

---

139	4.1	The four alignment levels for each of the detector subsystems. The total number of alignable structures and degrees of freedom (DoF) to be aligned are given for each level.	12
140			
141	4.2	Summary of the highest level of alignment applied to each ID subsystem when deriving the June alignment. . . . .	15
142			
143	4.3	Estimated value of the error scaling term $b$ for each subdetector component with the June alignment. . . . .	22
144			
145	5.1	Predicted cross sections for EQK and QCD production of diboson processes relevant to VBS at $\sqrt{s} = 8\text{TeV}$ using the <b>SHERPA</b> MC generator. Loose generator level cuts are applied on lepton $p_T > 5\text{ GeV}$ , dilepton invariant mass $m_{ll} > 4\text{ GeV}$ , and at least two jets with $m_{jj} > 10\text{ GeV}$ . . . . .	32
146			
147	5.2	Summary of MC samples used in the analysis. . . . .	37
148			
149	5.3	Muon selection criteria. All muons are required to pass the preselection (top), and then either the signal (middle) or loose (bottom) criteria is applied to the preselected electrons. . . . .	38
150			
151	5.4	Electron selection criteria. All electrons are required to pass the preselection (top), and then either the signal (middle) or loose (bottom) criteria is applied to the preselected electrons. . . . .	40
152			
153	5.5	Jet selection criteria. All jets are required to pass the above selection in order to be used in the analysis. . . . .	40
154			
155	5.6	Summary of the overlap removal procedure used in the analysis. If the criteria in the “check” column is met, in the “result” column, the object on the left of the arrow is removed in favor of the object on the right. . . . .	41
156			
157	5.7	Summary of trigger requirements for electrons and muons for $\sqrt{s} = 13\text{TeV}$ data collected in 2015 and 2016. At least one of the triggers must be satisfied. . . . .	42
158			
159	5.8	The signal event selection. . . . .	43
160			
161	5.9	Event yields in the $WZ$ control region before normalization. All lepton flavor channels are combined. . . . .	44
162			
163	5.10	Selection criteria for the $V\gamma$ control region. . . . .	45
164			
165	5.11	Event yields in the $V\gamma$ control region. The $V\gamma$ scale factor of 1.77 is calculated by scaling up the $Z\gamma$ and $Z+\text{jets}$ backgrounds to account for the difference between the data and predicted total background. . . . .	46
166			
167	5.12	Selection criteria for the same-sign inclusive validation region. . . . .	49
168			
169			

---

170	5.13	Event selection for the dijet region used for calculating the fake factor. The selected lepton can pass either the nominal (signal) or loose selections. In the case of the nominal leptons, the $p_T > 27$ GeV requirement is replaced with $p_T > 15$ GeV. . . . .	55
171			
172	5.14	Values of the fake factor in each $p_T$ bin and for each individual systematic source. . . . .	59
173			
174	5.15	Estimated yields for the fake lepton background. The estimated yield is shown in the first column together with the statistical uncertainty followed by the systematic uncertainties from variations of the the fake factors within their statistical (stat.) and systematic (syst.) uncertainties. The labels $f_e$ and $f_\mu$ indicate the fake factors for electrons and muons, respectively. . . . .	59
175			
176	5.16	Selection criteria for the same-sign top fakes validation region. . . . .	60
177			
178	5.17	Custom OR definition. Leptons must pass this selection in order to be counted for the trilepton veto. . . . .	66
179			
180	5.18	Definition of the fiducial volume. . . . .	69
181			
182	5.19	Impact of various systematic effects on the fiducial cross section measurement. The impact of a given source of uncertainty is computed by performing the fit with the corresponding nuisance parameter varied up or down by one standard deviation from its nominal value. . . . .	71
183			
184	5.20	List of sources of experimental uncertainties on the reconstruction of physics objects. . . . .	72
185			
186	5.21	Impact of experimental uncertainties for the $W^\pm W^\pm jj$ EWK processes in all channels. . . . .	73
187			
188	5.22	Impact of experimental uncertainties for the $WZ$ process in all channels. . . . .	73
189			
190	5.23	The set of generator level cuts used for generating the interference samples with <code>MadGraph</code> . . . . .	74
191			
192	5.24	Cross sections for each different $W^\pm W^\pm jj$ production mode (inclusive, EWK only, QCD only, and interference only) generated using <code>MadGraph</code> . The cross sections are calculated using a minimal set of generator level cuts from events where the $W$ decays to a muon. . . . .	74
193			
194	5.25	Table of the data and prediction event yields in the signal region before the fit. Numbers are shown for the six lepton flavor and charge channels and for all channels combined. Here the $WZ$ background yields are normalized to the data in the $WZ$ control region. The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from $V\gamma$ production and electron charge misidentification are combined in the “ $e/\gamma$ conversions” category. Finally, $ZZ$ , $VVV$ , and $t\bar{t}V$ backgrounds are combined in the “Other prompt” category. . . . .	75
195			
196			
197			
198			
199			
200			
201	5.26	Table of the data and prediction event yields in the signal region after the fit. Numbers are shown for the six lepton flavor and charge channels and for all channels combined. The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from $V\gamma$ production and electron charge misidentification are combined in the “ $e/\gamma$ conversions” category. Finally, $ZZ$ , $VVV$ , and $t\bar{t}V$ backgrounds are combined in the “Other prompt” category. . . . .	76
202			
203			
204			
205			
206			
207	6.1	Summary of MC samples used in the analysis. . . . .	83
208	6.2	Truth-based isolation requirements for electrons and muons. . . . .	84
209	6.3	Summary of the signal event selection. . . . .	86
210	6.4	Updates to the $W^\pm W^\pm jj$ event selection criteria after optimization. Cuts not listed remain unchanged from the default selection in Table 6.3. . . . .	90
211			
212	6.5	Signal and background event yields using the default event selection for an integrated luminosity of $\mathcal{L} = 3000 \text{ fb}^{-1}$ . Events containing a fake or charge-flipped electron are removed from their respective sources and combined into a single entry each. . . . .	94
213			
214			
215	6.6	Signal and background event yields using the optimized event selection for an integrated luminosity of $\mathcal{L} = 3000 \text{ fb}^{-1}$ . Events containing a fake or charge-flipped electron are removed from their respective sources and combined into a single entry each. . . . .	94
216			
217			

218	6.7 Summary of estimated experimental and rate uncertainties. . . . .	96
219	A.1 Event yields prior to applying any form of truth-based isolation criteria. . . . .	102
220	A.2 Event yields after applying a test version of the truth-based isolation. . . . .	102
221	B.1 Experimental systematics uncertainties for the $W^\pm W^\pm jj$ QCD processes in all channels.	103
222	B.2 Experimental systematics uncertainties for triboson process in all channels. . . . .	103
223	B.3 Experimental systematics uncertainties for $t\bar{t}V$ processes in all channels. . . . .	104
224	B.4 Experimental systematics uncertainties for the $W\gamma$ process in all channels. . . . .	104
225	B.5 Experimental systematics uncertainties for the $Z\gamma$ process in all channels. . . . .	104
226	B.6 Experimental systematics uncertainties for the $ZZ$ process in all channels. . . . .	104

# List of Figures

---

228	3.1	General cut-away view of the ATLAS detector.	4
229	4.1	Graphical representation of the effect of a misaligned detector element. The reconstructed particle track (dashed arrow) differs from the actual trajectory of the particle (solid arrow) due to the shift in one of the detector elements. The cyan lines represent the track-to-hit residuals.	7
230	4.2	Graphical representation of the ID alignment chain.	10
231	4.3	A schematic representation of the Inner Detector in the longitudinal plane with the global coordinate system overlaid on top. The Pixel detector and IBL are shown in blue, the SCT in green, and the TRT in red. The local coordinates for each subdetector module are inset on the right. Image taken from [1].	13
232	4.4	The $d_0$ distributions with respect to the reconstructed primary vertex using the $\sqrt{s} = 13\text{TeV}$ collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.	16
233	4.5	Local $x$ (left) and local $y$ (right) residual distributions of the IBL planar sensors using the $\sqrt{s} = 13\text{TeV}$ collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.	17
234	4.6	The mean of the local $x$ (left) and local $y$ (right) residual distributions as a function of the global $z$ position of each IBL module using the $\sqrt{s} = 13\text{TeV}$ collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red).	18
235	4.7	Local $x$ (top) and local $y$ (bottom) residual distributions for the Pixel barrel (excluding the IBL, left) and end-caps (right) using the $\sqrt{s} = 13\text{TeV}$ collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.	19
236	4.8	Local $x$ residual distributions for the SCT barrel (left) and end-caps (right) using the $\sqrt{s} = 13\text{TeV}$ collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.	20

259	4.9	Residual distributions for the TRT barrel (left) and end-caps (right) using the $\sqrt{s} = 13\text{TeV}$ collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries. . . . .	20
260			
261			
262			
263	4.10	Representation of splitting a single cosmic ray track passing through the entire detector (left) into two separate tracks (right). . . . .	21
264			
265	4.11	Distribution of the difference in the impact parameter $\Delta d_0$ (left) and charge over transverse momentum $\Delta q/p_T$ (right) between the two cosmic ray split tracks. The June (black) and March (green) alignments are compared. The distributions are normalized to the same number of entries. . . . .	21
266			
267			
268			
269	4.12	Pull distributions in local $x$ (left) and $y$ (right) for the IBL using the $\sqrt{s} = 13\text{TeV}$ collision data sample after applying the error scaling. . . . .	22
270			
271	4.13	Representation of a curl distortion in the detector. The image shows a cutaway in the transverse plane. The deformation is represented by the red arrows, and the impact on the reconstructed positive (blue) and negative (green) tracks are shown. The dashed lines represent the true particle trajectories, and the solid lines represent the reconstructed trajectories. . . . .	24
272			
273			
274			
275			
276	4.14	Geometric definition of the sagitta $s$ in relation to the length of the chord $l$ and the radius $r$ of a circular arc. . . . .	24
277			
278	4.15	$E/p$ distributions of electrons and positrons in two different $\eta\phi$ bins of the detector. The left hand plot is taken from a region with no momentum bias where $\langle E/p \rangle^+ = \langle E/p \rangle^-$ , while the right hand plot shows an 8% disagreement in $\langle E/p \rangle$ between electrons and positrons. . . . .	26
279			
280			
281			
282	4.16	Sagitta bias in the $\sqrt{s} = 13\text{TeV}$ data collected by ATLAS in 2016 as a function of $\eta$ and $\phi$ for the prompt (left) and reprocessed (right) alignments using the $E/p$ method. . . . .	27
283			
284	4.17	Sagitta bias in the $\sqrt{s} = 13\text{TeV}$ data collected by ATLAS in 2016 projected along $\eta$ for the prompt (gray) and reprocessed (blue) alignments using the $E/p$ method. . . . .	27
285			
286	4.18	Sagitta bias in the $\sqrt{s} = 13\text{TeV}$ data collected by ATLAS in 2017 as a function of $\eta$ and $\phi$ in reconstructed electrons (left) and after two iterations of momentum corrections (right) from the $E/p$ method. . . . .	28
287			
288			
289	4.19	Sagitta bias in the $\sqrt{s} = 13\text{TeV}$ data collected by ATLAS in 2017 projected along $\eta$ in reconstructed electrons (gray) and after one (red) and two (blue) iterations of momentum corrections from the $E/p$ method. . . . .	28
290			
291			
292	5.1	Cross sections in nanobarns for five different scattering processes of longitudinally polarized vector bosons as a function of center of mass energy $\sqrt{s}$ . Without a SM Higgs boson (left), the cross sections grow unbounded with $\sqrt{s}$ ; however with a 120 GeV Higgs boson (right), the cross sections no longer diverge. . . . .	30
293			
294			
295			
296	5.2	Tree-level Feynman diagrams for VBS EWK $VVjj$ production including triple gauge couplings involving $W$ and/or $Z$ bosons (top left and top middle), quartic gauge coupling (top right), or the exchange of a Higgs boson ( $s$ -channel bottom left and $t$ -channel bottom right). The labels are quarks ( $q$ ), fermions ( $f$ ), and gauge bosons ( $V = W, Z$ ). . . . .	31
297			
298			
299			
300	5.3	Tree-level Feynman diagrams for non-VBS EWK $VVjj$ production. The labels are quarks ( $q$ ), fermions ( $f$ ), and gauge bosons ( $V = W, Z$ ). . . . .	31
301			
302	5.4	Tree-level Feynman diagrams for QCD $VVjj$ production. The labels are quarks ( $q$ ), fermions ( $f$ ), and gauge bosons ( $V = W, Z$ ). . . . .	32
303			
304	5.5	Feynman diagrams for VBS EWK production of $W^\pm W^\pm jj$ events. The leftmost diagram contains a quartic gauge coupling vertex, and the rightmost diagram contains an exchange of a Higgs boson. <b>TODO: Make diagrams consistent with others</b> . . . . .	33
305			
306			

307	5.6	$W^\pm W^\pm jj$ VBS event topology containing two leptons (1 and 2) with the same electric charge, two neutrinos, and two forward tagging jets (3 and 4) with large rapidity separation $\Delta y$ . . . . .	33
310	5.7	Generator level comparisons at $\sqrt{s} = 8\text{TeV}$ of dijet invariant mass ( $m_{jj}$ , left) and dijet rapidity ( $\Delta y_{jj}$ , right) in EWK (red) and QCD (blue) $W^\pm W^\pm jj$ events. Both data sets have been normalized to the same area. . . . .	34
313	5.8	ATLAS event display of a $pp \rightarrow W^+W^+ \rightarrow \mu^+\nu_\mu\mu^+\nu_\mu jj$ event. The muons are represented by the red lines travelling from the ID through the MS, and the forward jets are represented by the blue cones with yellow energy deposits in the calorimeters. The direction of the $E_T^{\text{miss}}$ in the transverse plane is indicated by the gray dashed line in the inset image. Event display taken from [2]. . . . .	34
318	5.9	Leading lepton $p_T$ (left) and $\eta$ (right) distributions in the $WZ$ control region before normalization. All lepton channels are combined. . . . .	45
320	5.10	Trilepton invariant mass $m_{lll}$ distribution in the $WZ$ control region before normalization. All lepton channels are combined. . . . .	45
322	5.11	Charge misidentification rates for electrons as a function of $ \eta $ and $p_T$ . Rates are calculated from $Z \rightarrow e^+e^-$ MC after applying scale factors to approximate the charge mis-ID rates in data. . . . .	47
325	5.12	Dilepton invariant mass distribution $m_{ll}$ for the $ee$ channel in the same-sign inclusive VR. . . . .	49
326	5.13	$p_T$ distributions for the leading (left) and subleading (right) electron for the $ee$ channel in the same-sign inclusive VR. In these plots, the cut requiring $m_{ee}$ to fall within the $Z$ mass window has been inverted in order to test the modelling away from the $Z$ peak. . . . .	50
329	5.14	$\Delta p_T$ distributions for nominal (blue) and loose (red) muons in simulated $t\bar{t}$ events. Each muon has been matched to a truth-level jet. Both distributions are normalized to unit area. . . . .	52
332	5.15	$\Delta p_T$ distributions for muons (top) and electrons (bottom) in simulated $t\bar{t}$ events. Each lepton has been matched to a truth-level jet, and that truth jet has had its $p_T$ corrected to include all truth muons within a cone of $\Delta R < 0.4$ . The nominal leptons are in black. $\Delta p_T$ is calculated for the loose leptons using $p_T$ (red) and $p_T + p_T^{\text{cone}}$ (blue). . . . .	54
336	5.16	Distributions of $p_T^{\text{cone}}/p_T$ for nominal (black) and loose (red) muons in simulated $t\bar{t}$ events. . . . .	55
337	5.17	The measured fake factor as a function of muon $p_T + p_T^{\text{cone}}$ . The error bars represent the statistical uncertainty only. . . . .	56
339	5.18	The measured fake factor as a function of electron $p_T + p_T^{\text{cone}}$ in the central ( $ \eta  < 1.37$ , blue) and forward ( $ \eta  > 1.37$ , red) regions of the detector. The error bars represent the statistical uncertainty only. . . . .	56
342	5.19	Graphical representation of the fake factor application using $p_T + p_T^{\text{cone}}$ . The value of $p_T + p_T^{\text{cone}}$ for the loose lepton is used to “look up” the fake factor weight which is then applied to the event. The loose lepton’s $p_T$ becomes $p_T + p_T^{\text{cone}}$ for the purpose of the fake background estimation. . . . .	57
346	5.20	Systematic variations in the fake factor as a function of muon $p_T + p_T^{\text{cone}}$ . The individual fake factors obtained for each systematic variation are displayed with their statistical uncertainties. . . . .	60
349	5.21	Systematic variations in the fake factor as a function of electron $p_T + p_T^{\text{cone}}$ in the central ( $ \eta  < 1.37$ , top) and forward ( $ \eta  > 1.37$ , bottom) regions of the detector. The individual fake factors obtained for each systematic variation are displayed with their statistical uncertainties. . . . .	61
353	5.22	Distributions of the subleading lepton $p_T$ in the same-sign top fakes VR for $\mu^\pm\mu^\pm$ events (top right), $e^\pm e^\pm$ events (top left), $\mu^\pm e^\pm$ events (bottom left), and all events combined (bottom right). All errors are statistical only. . . . .	62

356	5.23 Pseudorapidity ( $\eta$ ) distributions of truth muons (top) and electrons (bottom) for Sherpa $W^\pm W^\pm jj$ and $WZ$ MC samples. The blue vertical lines represent the allowed $\eta$ range for each lepton flavor. The numbers correspond to the number of raw MC events that fall within and outside of the allowed $\eta$ range for each MC sample. . . . .	64
360	5.24 Distributions of $p_{T,\text{ratio}}(\mu, j)$ for EWK and QCD $W^\pm W^\pm jj$ signal (black) and $WZ$ back- ground (teal) for truth-matched third muons in events that pass the trilepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on $p_{T,\text{ratio}}(\mu, j)$ at a given value on the $x$ -axis. . . . .	64
365	5.25 Distributions of $\Delta R(\mu, j)$ for EWK and QCD $W^\pm W^\pm jj$ signal (black) and $WZ$ back- ground (teal) for truth-matched third muons in events that pass the trilepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on $\Delta R(\mu, j)$ at a given value on the $x$ -axis. . . . .	65
370	5.26 Distributions of $p_{T,\text{ratio}}(e, j)$ for EWK and QCD $W^\pm W^\pm jj$ signal (black) and $WZ$ back- ground (teal) for truth-matched third electrons in events that pass the trilepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on $p_{T,\text{ratio}}(e, j)$ at a given value on the $x$ -axis. . . . .	65
375	5.27 Two-dimensional plots of $p_{T,\text{ratio}}(\mu, j)$ vs $\Delta R(\mu, j)$ for truth-matched third muons in events that pass the trilepton veto for EWK and QCD $W^\pm W^\pm jj$ signal (left) and $WZ$ background (right). The blue overlay indicates the area in which the third leptons will pass the custom OR and result in the event failing the trilepton veto. . . . .	66
379	5.28 Visual representation of the different kinematic regions relevant to the cross section mea- surement. The acceptance factor $\mathcal{A}$ converts from the truth level total phase space to the truth level fiducial region, and the efficiency correction $\mathcal{C}$ translates the fiducial region in to the reconstruction level signal region. . . . .	70
383	5.29 The dijet invariant mass $m_{jj}$ distributions for data and predicted signal and background in the signal region after the fit. The shaded band represents the statistical and systematic uncertainties added in quadrature. Note that the bins have been scaled such that they represent the number of events per 100 GeV in $m_{jj}$ . The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from $V\gamma$ production and electron charge misidentification are combined in the “ $e/\gamma$ conversions” category. Finally, $ZZ$ , $VVV$ , and $t\bar{t}V$ backgrounds are combined in the “Other prompt” category. . . . .	76
391	5.30 The event yields for data and predicted signal and background in the $WZ$ and low- $m_{jj}$ control regions after the fit. The shaded band represents the statistical and systematic uncertainties added in quadrature. The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from $V\gamma$ production and electron charge misidentification are combined in the “ $e/\gamma$ conversions” category. Finally, $ZZ$ , $VVV$ , and $t\bar{t}V$ backgrounds are combined in the “Other prompt” category. . . . .	77
397	5.31 Comparison of the measured $W^\pm W^\pm jj$ EWK fiducial cross section with theoretical cal- culations from SHERPA v2.2.2 and POWHEG-BOX v2. The light orange band represents the total experimental uncertainty on the measured value, and the dark orange hashed band is the statistical uncertainty. For the simulations, the light blue band represents the total theoretical uncertainty, and the dark blue hashed band are the scale uncertain- ties. The theory predictions do not include the interference between the EWK and QCD production. . . . .	78

404	6.1	Comparison of the leading (top) and subleading (bottom) lepton $p_T$ distributions for purely longitudinal (LL, black) and mixed polarization (LT+TT, cyan) $W^\pm W^\pm jj$ events.	82
405	6.2	Comparison of the azimuthal dijet separation ( $ \Delta\phi_{jj} $ ) for purely longitudinal (LL, black) and mixed polarization (LT+TT, cyan) $W^\pm W^\pm jj$ events. . . . .	83
406	6.3	A visual representation of a rectangular grid search algorithm. The signal events are the blue triangles, and the red circles are the background events. <b>TODO: replace with own figure</b> . . . . .	87
407	6.4	A visual representation of a random grid search algorithm. The signal events are the blue triangles, and the red circles are the background events. <b>TODO: replace with own figure</b> . . . . .	88
408	6.5	Leading lepton $p_T$ distribution. The default and optimized cuts are represented by the red and green dashed lines, respectively. The $W^\pm W^\pm jj$ EWK signal (black points) is normalized to the same area as the sum of the backgrounds (colored histogram). <b>TODO: Move to appendix or omit</b> . . . . .	91
409	6.6	Dilepton invariant mass distribution. The default and optimized cuts are represented by the red and green dashed lines, respectively. The $W^\pm W^\pm jj$ EWK signal (black points) is normalized to the same area as the sum of the backgrounds (colored histogram). <b>TODO: Move to appendix or omit</b> . . . . .	91
410	6.7	Leading (top) and subleading (bottom) jet $p_T$ distributions. The default and optimized cuts are represented by the red and green dashed lines, respectively. The $W^\pm W^\pm jj$ EWK signal (black points) is normalized to the same area as the sum of the backgrounds (colored histogram). . . . .	92
411	6.8	Dijet invariant mass distribution. The default and optimized cuts are represented by the red and green dashed lines, respectively. The $W^\pm W^\pm jj$ EWK signal (black points) is normalized to the same area as the sum of the backgrounds (colored histogram). <b>TODO: Move to appendix or omit</b> . . . . .	93
412	6.9	Lepton-jet centrality distribution. The default and optimized cuts are represented by the red and green dashed lines, respectively. The $W^\pm W^\pm jj$ EWK signal (black points) is normalized to the same area as the sum of the backgrounds (colored histogram). . . . .	93
413	6.10	$p_T$ distributions for the leading jet using the default (left) and optimized (right) event selections for all channels combined. . . . .	95
414	6.11	$p_T$ distributions for the subleading jet using the default (left) and optimized (right) event selections for all channels combined. . . . .	95
415	6.12	$p_T$ distributions for lepton-jet centrality $\zeta$ using the default (left) and optimized (right) event selections for all channels combined. . . . .	95
416	6.13	Projections of the statistical (black), theoretical (blue), systematic (yellow), and total (red) uncertainties on the measured cross section as a function of integrated luminosity using the optimized event selection. . . . .	97
417	6.14	Dijet azimuthal separation ( $ \Delta\phi_{jj} $ ) for the low $m_{jj}$ region ( $520 < m_{jj} < 1100$ GeV, top) and the high $m_{jj}$ region ( $m_{jj} > 1100$ GeV, bottom). The purely longitudinal (LL, gray) is plotted separately from the mixed and transverse (LT+TT, cyan) polarizations. . . . .	99
418	6.15	Projections of the expected longitudinal scattering significance as a function of integrated luminosity when considering all sources of uncertainties (black) or only statistical uncertainties (red). . . . .	100

# LHC and the ATLAS Detector

---

467

## 3.1 The Large Hadron Collider

468

The Large Hadron Collider (LHC) [5] is...

469

## 3.2 The ATLAS Detector

470

ATLAS is a general-purpose particle detector...

471

### 3.2.1 The Inner Detector

472

The Inner Detector serves the primary purpose of measuring the trajectories of charged particles...

473

#### 3.2.1.1 Pixel Detector

474

The Pixel detector consists of four cylindrical barrel layers and three disk-shaped endcap layers...

475

#### 3.2.1.2 Semiconductor Tracker

476

The Semiconductor Tracker uses the same basic technology as the Pixels, but the fundamental unit

477

of silicon is a larger “strip”...

478

#### 3.2.1.3 Transition Radiation Tracker

479

The Transition Radiation Tracker is the outermost component of the ID...

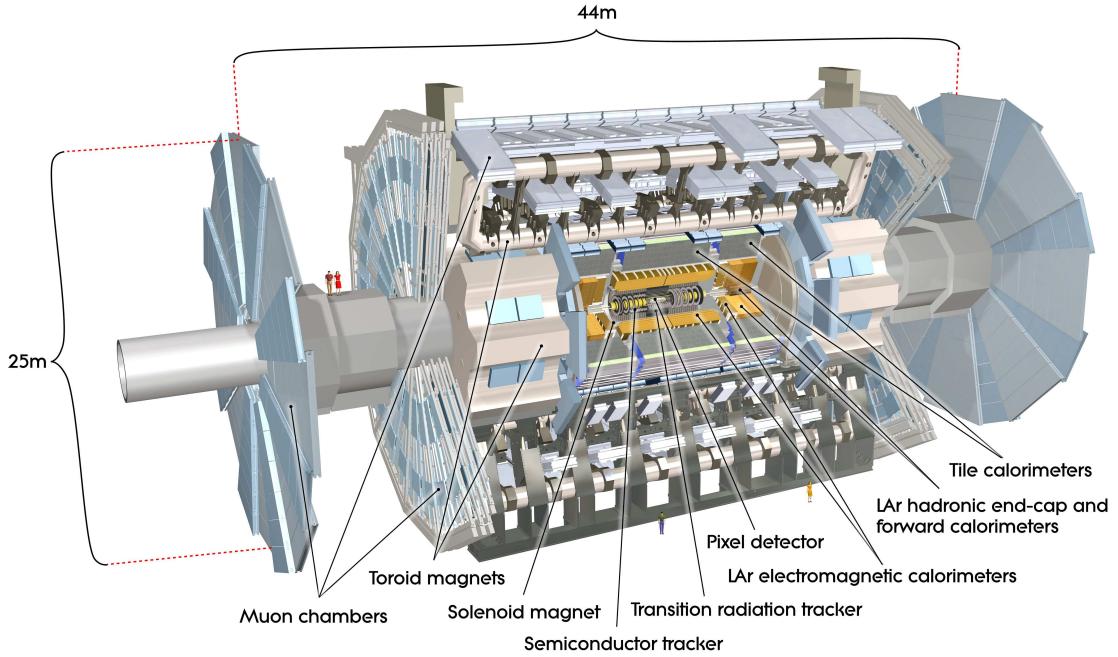

Figure 3.1: General cut-away view of the ATLAS detector [6].

### 480 3.2.2 The Calorimeters

481 ATLAS includes two types of calorimeter system for measuring electromagnetic and hadronic showers.  
 482 These are the Liquid Argon (LAr) calorimeters and the Tile calorimeters. Together, these cover  
 483 the region with  $|\eta| < 4.9\dots$

#### 484 3.2.2.1 Liquid Argon Calorimeters

485 The Liquid Argon system consists of...

#### 486 3.2.2.2 Tile Calorimeters

487 The Tile calorimeter provides coverage for hadronic showers...

### 488 3.2.3 The Muon Spectrometer

489 Muon spectrometer stuff.

490 **3.2.4 Particle reconstruction**

491 Particle reconstruction algorithms

492 **3.2.4.1 Track reconstruction**

493 **3.2.4.2 Muon reconstruction**

494 **3.2.4.3 Electron reconstruction**

495 **3.2.4.4 Jet reconstruction**

## CHAPTER 4

---

# Alignment of the ATLAS Inner Detector

---

498 When a charged particle passes through the ATLAS ID, it leaves hits in the sensors along its path.  
 499 In order to accurately measure the track of the particle, it is necessary to know where these hits  
 500 occurred as precisely as possible, which in turn requires knowledge of the physical location of the  
 501 element that registered the hit. If one of these elements is *misaligned*, or displaced relative to  
 502 its position in the known detector geometry, the assumed location of the corresponding hit will  
 503 not match its actual location, resulting in an incorrect track fit. These misalignments can occur for  
 504 any number of reasons, including but not limited to elements shifting during maintenance periods or  
 505 cycles in ATLAS's magnetic field, or small movements during normal detector operations. The effect  
 506 of a misaligned detector element on the track reconstruction and the resulting track-hit residuals is  
 507 shown in Figure 4.1. **TODO: there has to be a better way to introduce this figure – i haven't talked**  
 508 **about residuals yet**

509 In order to correct the misalignments, the ID alignment procedure is applied to accurately  
 510 determine the physical position and orientation of each detector element. The baseline accuracy of  
 511 the alignment is required to be such that the track parameter resolutions are not degraded by more  
 512 than 20% with respect to those derived from a perfect detector geometry<sup>2</sup>. This corresponds to a  
 513 precision of better than  $10\mu\text{m}$  in the positioning of the elements of the silicon detectors [7].

514 This chapter outlines the ID alignment procedure, the alignment of the detector during the 2015  
 515 data taking period, and the steps taken to measure momentum biases in the alignment.

---

<sup>2</sup>The so-called *perfect geometry* refers to the description of the ATLAS detector in which every sensor precisely matches its design specifications. The perfect geometry contains no misalignments, and the position of each sensor is known exactly.

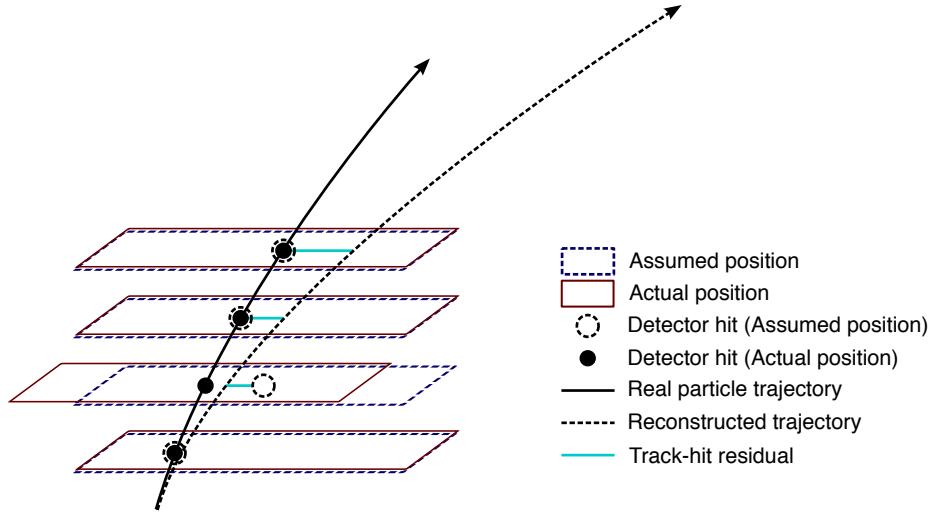

Figure 4.1: Graphical representation of the effect of a misaligned detector element. The reconstructed particle track (dashed arrow) differs from the actual trajectory of the particle (solid arrow) due to the shift in one of the detector elements. The cyan lines represent the track-to-hit residuals.

## 516 4.1 The alignment method

517 The alignment procedure uses track-based algorithm that updates the locations of detector elements  
 518 in order to minimize the set of track-hit *residuals*. These residuals are defined as the distance between  
 519 the fitted track position in a given detector element to the position of the hit recorded by the same  
 520 element. Tracks in ATLAS are parameterized as five-dimensional vectors [8]:

$$\vec{r} = (d_0, z_0, \phi_0, \theta, q/p) \quad (4.1)$$

521 where  $d_0$  and  $z_0$  are the transverse and longitudinal impact parameters with respect to the origin,  
 522 respectively,  $\phi_0$  is the azimuthal angle of the track at the point of closest approach to the origin,  $\theta$   
 523 is the polar angle, and  $q/p$  is the charge of the track divided by its momentum. The residual for the  
 524  $i^{\text{th}}$  hit of a given track can then be written in terms of the track parameters  $\vec{r}$  and a set of alignment  
 525 parameters  $\vec{a}$  that describe the hit location [9]:

$$r_i(\vec{r}, \vec{a}) = (\vec{m}_i - \vec{e}_i(\vec{r}, \vec{a})) \cdot \hat{k} \quad (4.2)$$

526 where  $\vec{e}_i$  is the intersection point of the extrapolated track with the sensor,  $\vec{m}_i$  is the position of the  
 527 associated hit within the sensor, and  $\hat{k}$  is the unit vector defining the direction of the measurement  
 528 within the sensor.  $\vec{r}$  is then the vector of residuals for the given track.

529 A  $\chi^2$  function can be built from the residuals of all collected tracks:

$$\chi^2 = \sum_{\text{tracks}} \vec{r}^T V^{-1} \vec{r} \quad (4.3)$$

530 where  $V$  is the covariance matrix of the hit measurements. The  $\chi^2$  function is then minimized with  
 531 respect to the alignment parameters  $\vec{a}$ , which contain all degrees of freedom being aligned. The  
 532 minimization condition with respect to  $\vec{a}$  is:

$$\frac{d\chi^2}{d\vec{a}} = 0 \rightarrow 2 \sum_{\text{tracks}} \left( \frac{d\vec{r}}{d\vec{a}} \right)^T V^{-1} \vec{r} = 0 \quad (4.4)$$

533 This equation can be difficult to solve exactly, so the residual is rewritten as a first order Taylor  
 534 expansion:

$$\vec{r} = \vec{r}_0 + \frac{d\vec{r}}{d\vec{a}} \delta\vec{a} \quad (4.5)$$

535 where  $\vec{r}_0$  is dependent on an initial set of track and alignment parameters  $\vec{r}_0$  and  $\vec{a}_0$ , respectively;  
 536 the track parameter dependence has also been folded into the total derivative  $\frac{d\vec{r}}{d\vec{a}}$ . Equation 4.5 can  
 537 then be inserted into the minimization condition from Equation 4.4 to give:

$$\left[ \sum_{\text{tracks}} \left( \frac{d\vec{r}}{d\vec{a}} \right)^T V^{-1} \left( \frac{d\vec{r}}{d\vec{a}} \right) \right] \delta\vec{a} + \sum_{\text{tracks}} \left( \frac{d\vec{r}}{d\vec{a}} \right)^T V^{-1} \vec{r}_0 = 0 \quad (4.6)$$

538 From this equation, the alignment matrix  $\mathcal{M}_a$  and alignment vector  $\vec{\nu}_a$  can be defined:

$$\mathcal{M}_a = \sum_{\text{tracks}} \left( \frac{d\vec{r}}{d\vec{a}} \right)^T V^{-1} \left( \frac{d\vec{r}}{d\vec{a}} \right) \quad (4.7)$$

539

$$\vec{\nu}_a = \sum_{\text{tracks}} \left( \frac{d\vec{r}}{d\vec{a}} \right)^T V^{-1} \vec{r}_0 \quad (4.8)$$

540 Finally, the alignment corrections  $\delta\vec{a}$  can be solved for by inverting the alignment matrix:

$$\delta\vec{a} = -\mathcal{M}_a^{-1} \vec{\nu}_a \quad (4.9)$$

541 which is a linear system of equations with a number of equations equal to the number of alignment  
 542 degrees of freedom [10].

543 Inverting the matrix and solving this system of equations is referred to as *Global  $\chi^2$  alignment* [9].  
 544 This can be useful, as  $\mathcal{M}_a$  contains all the correlations between the alignable structures. However,  
 545 inverting the matrix becomes difficult when the number of degrees of freedom becomes large, and  
 546 as the number of alignable structures increases, so too does the size of the matrix  $\mathcal{M}_a$ . Eventually  
 547 inverting the matrix becomes too computationally intensive to be practical.

548 This problem is solved by the *Local*  $\chi^2$  algorithm [11]. In this case, the alignment matrix is  
 549 constructed to be block-diagonal, allowing for it to be inverted even for large numbers of degrees of  
 550 freedom. This is achieved by replacing the full derivative in Equation 4.6 with the partial derivative  
 551  $\frac{\partial \vec{r}}{\partial \vec{a}}$ . The new alignment matrix  $\mathcal{M}'_a$  and alignment vector  $\vec{\nu}'_a$  become:

$$\mathcal{M}_a = \sum_{\text{tracks}} \left( \frac{\partial \vec{r}}{\partial \vec{a}} \right)^T V^{-1} \left( \frac{\partial \vec{r}}{\partial \vec{a}} \right) \quad (4.10)$$

$$\vec{\nu}_a = \sum_{\text{tracks}} \left( \frac{\partial \vec{r}}{\partial \vec{a}} \right)^T V^{-1} \vec{r}_0 \quad (4.11)$$

552 553 Inverting  $\mathcal{M}'_a$  is considerably faster and less intensive even for large numbers of degrees of freedom;  
 554 however, the correlations between the alignable structures is lost.

555 Due to the Taylor expansion used in Equation 4.6, several iterations of the alignment algorithm  
 556 may be necessary to converge on a final set of alignment constants. The Local  $\chi^2$  alignment typically  
 557 requires more iterations due to the loss of the correlation information [12]. In practice, the ATLAS  
 558 reconstruction is run over a set of events, and the resulting tracks are fed to the alignment algorithm.  
 559 The residuals are calculated, the alignment matrix is built and inverted, and a new set of alignment  
 560 constants is obtained. The convergence of the alignment can be checked by:

561 1. Measure the  $\Delta\chi^2$  with the previous iteration. If it is near zero, then the  $\chi^2$  is approaching its  
 562 minimum.

563 2. Looking at the residual distributions for different alignable structures. A well aligned detector  
 564 will have a mean residual of zero with a width approximating the intrinsic resolution of the  
 565 detector.

566 If the above checks are satisfied, the process is finished and the final alignment constants are read  
 567 out; if not, another iteration is performed. A visual representation of the alignment chain is shown  
 568 in Figure 4.2.

569 Since a  $\chi^2$  minimization is used to align the detector, if there is a systematic misalignments in  
 570 the detector that does not adversely affect the  $\chi^2$ , the algorithm will be insensitive to it. These  
 571 misalignments are referred to as *weak modes*, and special care is taken to remove them [13]. One  
 572 potential impact of weak modes is a bias in the track momentum of reconstructed particles. This  
 573 particular effect is the subject of Section 4.3.

574 In practice, the detector is aligned both in “real-time” as data is collected, and during dedicated  
 575 offline alignment campaigns. The real-time alignment is run in ATLAS’s so-called *calibration loop*,

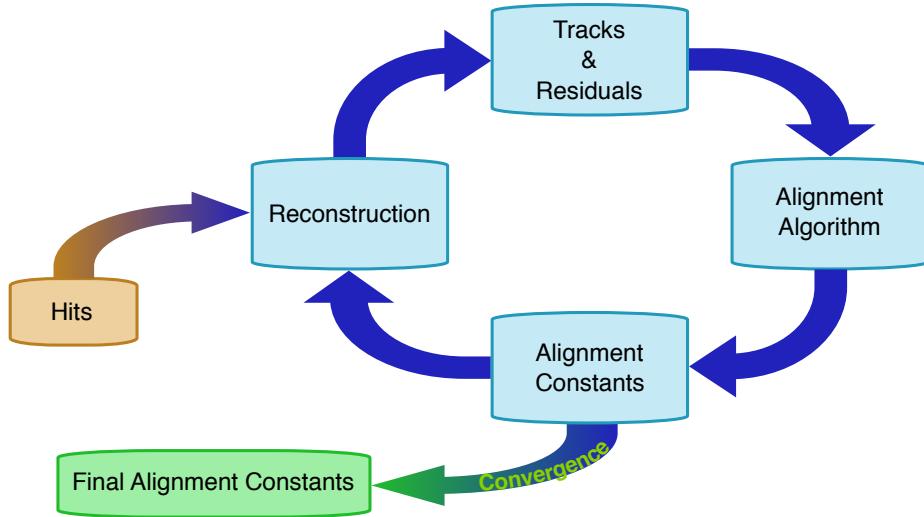

Figure 4.2: Graphical representation of the ID alignment chain.

576 which comprises the first stage in the preparation of data for physics analysis. The calibration loop  
 577 requires the alignment as well as various other detector calibrations to be available within 48 hours  
 578 for initial data processing. A fast, coarse-grained alignment<sup>3</sup> is run on a subset of the available  
 579 data containing full tracking information, and the results are propagated to the reconstruction of  
 580 that particular run [14]. Due to the time constraints of the calibration loop, a full sensor-by-sensor  
 581 alignment is not possible.

582 The more thorough and finely tuned alignments are reserved for the dedicated alignment cam-  
 583 paigns. These generally occur early in data taking campaigns, typically once a sufficient amount  
 584 of data is collected after a detector shutdown, in order to obtain a good baseline alignment for use  
 585 in the remainder of the data collection period. Once data taking is complete, another campaign  
 586 determines an improved set of alignment constants (divided into several “blocks” to account for  
 587 time-dependent misalignments), and the full data is reprocessed using the newly derived detector  
 588 geometry. The initial offline alignment of the ATLAS detector at the beginning of Run 2 in 2015 is  
 589 the subject of Section 4.2.

#### 590 4.1.1 Alignment levels

591 The alignment of the detector is performed at several levels of increasing granularity. This adds  
 592 flexibility in being able to align only as finely as needed, and it also allows for global, detector-level

---

<sup>3</sup>The calibration loop runs up to a Level 2 alignment in the silicon detectors, which involves treating each layer of sensors as a single object, defined in greater detail in Table 4.1.

593 misalignments to be corrected first before dealing with finer adjustments.

- 594     • Level 1 (L1) alignment involves moving entire subdetector components as a single unit, such  
595         as the entire Pixel detector, or the SCT barrel. These often have the largest misalignments,  
596         but they are easily corrected and do not require large volumes of data to do so.
- 597     • Level 2 (L2) alignment treats individual layers in the silicon detectors (modules in the TRT)  
598         and end cap disks as individual alignable objects.
- 599     • Level 2.7 (L27) alignment was introduced with the addition of the IBL to the ID in Run 2. It  
600         involves the stave-by-stave alignment of the IBL and Pixel barrel<sup>4</sup>.
- 601     • Level 3 (L3) alignment treats each sensor in the silicon detectors and each straw in the TRT  
602         as an individual alignable object. It is the finest grained alignment available but also the most  
603         computationally intensive due to the large number of degrees of freedom. The large number  
604         of individual detector sensors being aligned also requires the largest amount of statistics.

605 The different alignment levels are listed in more detail in Table 4.1, including the number of alignable  
606 structures and associated degrees of freedom for each detector component.

607 The implementation of the alignment algorithm in the software is flexible enough to allow each  
608 subsystem to be aligned individually at a specified level. Each alignable structure has six degrees of  
609 freedom: 3 translations ( $T_x, T_y, T_z$ ) and 3 rotations ( $R_x, R_y, R_z$ )<sup>5</sup>; however individual degrees of  
610 freedom may be turned on and off as required. In a typical alignment job, L1 and L2 contain few  
611 enough degrees of freedom that the Global  $\chi^2$  algorithm can be used, but L3 alignments (which can  
612 contain over 36,000 degrees of freedom in the silicon detectors alone) require the Local  $\chi^2$  algorithm.

#### 613 4.1.2 Alignment coordinate systems

614 The global coordinate system ( $x, y, z$ ) used by the ID alignment matches that of the ATLAS  
615 detector in general, as detailed in Section 3.2 **TODO: update with actual location of figure when**  
616 **it's in....** The positions and orientations of individual detector modules of the ID are defined by  
617 a right-handed local coordinate system ( $x', y', z'$ ) where the origin is defined as the geometrical  
618 center of the module. The  $x'$ -axis for each silicon module is defined to point along the most sensitive

---

<sup>4</sup>For the purposes of this Chapter, the term “Pixel” will refer to the original three layers of the Pixel detector, and the IBL will be referenced separately.

<sup>5</sup>The TRT is an exception, as the subdetector does not have any resolution along the length of the straw. Therefore, for the barrel,  $T_z$  is omitted. Similarly for the straws themselves, only two parameters are defined: translation with respect to the radial direction ( $T_\phi$ ) and rotation with respect to the radial axis ( $R_r$  for the barrel and  $R_z$  for the end-caps) [15].

Level	Description of alignable structure	Structures	DoF	
1	IBL detector	1	6	
	Whole Pixel detector	1	6	
	SCT barrel and 2 end-caps	3	18	
	TRT barrel and 2 end-caps ( $T_z$ fixed)	3	17	
Total:		8	47	
2	IBL detector	1	6	
	Pixel barrel layers	3	18	
	Pixel end-cap disks	$2 \times 3$	36	
	SCT barrel layers	4	24	
	SCT end-cap disks	$2 \times 9$	108	
	TRT barrel 32 modules ( $T_z$ fixed)	$3 \times 32$	480	
	TRT end-cap wheels	$2 \times 40$	480	
Total:		208	792	
2.7	IBL staves	14	84	
	Pixel barrel staves	$22+38+52$	672	
	Pixel end-cap disks	$2 \times 3$	18	
	Total:		132	1,878
3	IBL modules	280	1,680	
	Pixel modules	1,744	10,464	
	SCT modules	4,088	24,528	
	TRT barrel wires ( $T_\phi, R_r$ only)	105,088	210,176	
	TRT end-cap wires ( $T_\phi, R_Z$ only)	245,760	491,520	
	Total silicon sensors:		6,112	36,672
	Total TRT wires:		350,848	701,696

Table 4.1: The four alignment levels for each of the detector subsystems. The total number of alignable structures and degrees of freedom (DoF) to be aligned are given for each level.

619 direction of the module, the  $y'$ -axis is oriented along the long side of the module, and the  $z'$ -axis is  
 620 orthogonal to the  $(x', y')$  plane. For the TRT straws, the  $x'$ -axis is perpendicular to both the wire  
 621 and the radial direction, defined from the origin of the global frame to the straw center, the  $y'$ -axis  
 622 points along the straw, and once again the  $z'$ -axis is orthogonal to the  $(x', y')$  plane. A depiction of  
 623 the global and local coordinate systems for the ID is shown in Figure 4.3.

624 When considering the alignment degrees of freedom listed earlier in Section 4.1.1, grouped collections  
 625 of modules, layers, or entire subdetectors use the global coordinate system; individual modules  
 626 use their respective local coordinate systems. The translations  $T_i$  are with respect to the origin of  
 627 the given reference frame, and the rotations  $R_i$  are taken about the Cartesian axes.

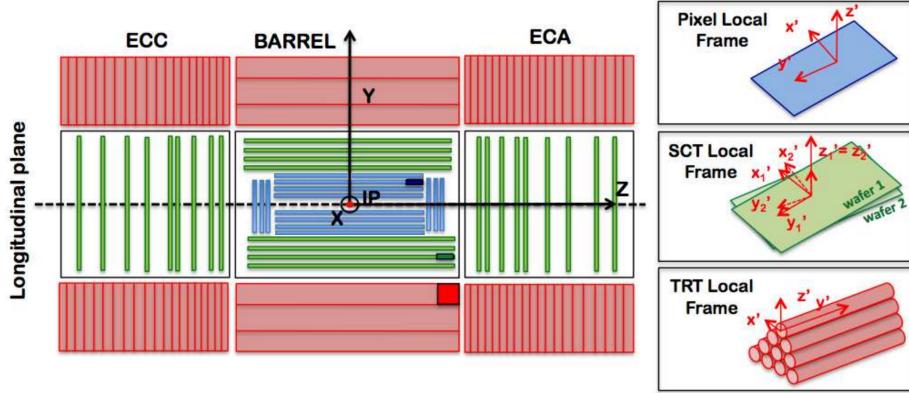

Figure 4.3: A schematic representation of the Inner Detector in the longitudinal plane with the global coordinate system overlaid on top. The Pixel detector and IBL are shown in blue, the SCT in green, and the TRT in red. The local coordinates for each subdetector module are inset on the right. Image taken from [1].

## 628 4.2 Early 2015 alignment of the ATLAS detector

629 At the end of Run 1, the LHC was shut down for upgrades and maintenance. During this time,  
 630 a number of upgrades were performed on the ATLAS detector, including the installation of a new  
 631 innermost layer of the Pixel detector, the Insertable B-Layer (IBL) [16]. **TODO: This will certainly**  
 632 **be defined in the detector description, so maybe the citation and abbreviation are not needed** These  
 633 changes to the ID required some detector components to be removed temporarily, and many elements  
 634 shifted relative to each other over the course of the maintenance process. In order to correct for  
 635 these large detector movements prior to  $\sqrt{s} = 13$  TeV collision data taking, an alignment was  
 636 performed using cosmic ray data collected in early 2015 [1]. This alignment was able to correct for  
 637 the majority of the large detector-wide misalignments as well as determine the global position of  
 638 the IBL at the micron level.

639 In June of 2015, shortly after the data taking period began, the first track-based alignment of  
 640 the refurbished ID was performed using  $\mathcal{L} = 7.9 \text{ pb}^{-1}$  of  $\sqrt{s} = 13$  TeV  $pp$  collision data [17].  
 641 Starting from the initial geometry determined by the cosmic ray alignment, referred to hereafter  
 642 as the *March alignment*, an improved set of alignment constants, called the *June alignment*, was  
 643 derived from a data set of approximately 1.4 million selected tracks. For comparison, a MC sample  
 644 containing approximately 2.7 million tracks was constructed from dijet events simulated using a  
 645 perfect detector geometry; the MC events are reweighted to match the  $\eta$  and  $p_T$  distributions found  
 646 in the data. Additional validation of the alignment results uses a set of cosmic ray data collected

647 by the detector during the LHC collisions. **TODO:** find some way of saying that this section follows  
 648 the alignment note [17]? or is it ok not to...

#### 649 4.2.1 June alignment procedure

650 The data set used as the input for the alignment contains a subset of physics events used for prompt  
 651 reconstruction recorded at a rate of 10 Hz. To ensure that only high quality tracks are used for the  
 652 alignment, each track is required to have transverse momentum  $p_T > 3$  GeV, contain at least one  
 653 hit in the Pixel detector, at least seven hits in the combined silicon detectors, and at least 25 hits  
 654 in the TRT.

655 A full L3 alignment of the IBL was included in the March alignment; however, a realignment  
 656 was necessary. Since the cosmic rays pass through the detector top-down, the staves on the sides of  
 657 the IBL could not be aligned as precisely as those on the top and bottom due to lower statistics.  
 658 Additionally, the IBL was operating at a temperature of  $-20^\circ\text{C}$  during the cosmic data taking  
 659 and at  $-10^\circ\text{C}$  for collision data taking. This proved to be significant, as it was observed that  
 660 the IBL staves experience a temperature-dependent, parabolic bowing in the local  $x'$ -direction of  
 661 approximately  $-10\mu\text{m}/\text{K}$  [18]. As a result, a full L3 alignment of the IBL was essential in order to  
 662 correct for the bowing. Due to it being a brand new element of the detector as well as its importance  
 663 in vertexing and  $b$  jet tagging, aligning the IBL sensors with a high degree of precision was of great  
 664 importance.

665 The June alignment was performed in two stages, with the first pass focusing on relative move-  
 666 ments of the big structures and correcting for the bowing of the IBL. The March alignment corrected  
 667 for these larger movements as well; however, it was observed during Run 1 that these sort of mis-  
 668 alignments are introduced by changing conditions in the detector [13], such as in the cooling system  
 669 or magnet power cycling, which may have occurred between the early cosmic data taking and the  
 670 first  $\sqrt{s} = 13$  TeV collisions. The silicon detectors were aligned at several different levels and the  
 671 IBL was aligned at the module level; the TRT detector was kept fixed to act as a global reference  
 672 frame. The full alignment chain for the first pass consisted of the following steps:

- 673 1. The IBL, Pixel, and SCT detectors were aligned at L1. The SCT barrel was not aligned in  
 674  $T_z$  in order to constrain global displacements along the  $z$ -axis, as the TRT is not sensitive to  
 675 that degree of freedom.
- 676 2. The IBL, and Pixel barrel and end-caps, and SCT barrel were aligned at L2. The SCT end-caps  
 677 were aligned at L1.

- 678     3. The IBL and pixel barrel were aligned at L27, using all six degrees of freedom. The Pixel  
 679       end-cap disks were only aligned in the plane ( $T_x$ ,  $T_y$ , and  $R_z$ ). The SCT was treated the same  
 680       as in the previous step.
- 681     4. The IBL was aligned at L3 using all six degrees of freedom for each module.

682       The primary goal for the second pass was to remove a bias in the transverse impact parameter  
 683        $d_0$  present in the March alignment. The resolution of  $d_0$  was also poorer than expected. In order  
 684       to correct for this, an additional constraint was passed to the alignment by adding an impact  
 685       parameter with respect to the beam spot as a pseudo-measurement [19]. When the alignment  
 686       algorithm minimizes the  $\chi^2$ , it will take care of the impact parameter minimization as well. Only  
 687       the IBL and Pixel detectors were aligned in this step. The stages of the second pass are listed below,  
 688       and the beam spot constraint was used in each:

- 689     1. The IBL and Pixel detectors were aligned at L2 with the SCT fixed.  
 690     2. The IBL was aligned at L27  
 691     3. The IBL and Pixel barrel and end-caps were aligned at L3.

692       The set of alignment constants obtained at the end of the second pass represents the June alignment.  
 693       The highest level of alignment over the course of the two passes for each subdetector is listed in  
 694       Table 4.2.

Detector	Highest level of alignment
IBL	L3
Pixel	Barrel
	End-caps
SCT	Barrel
	End-caps
TRT	None

Table 4.2: Summary of the highest level of alignment applied to each ID subsystem when deriving the June alignment.

### 695   4.2.2 Alignment results

696       The primary measure of alignment quality is assessed by looking at the track-hit residual distri-  
 697       butions. If the detector is well aligned, the residuals will be Gaussian-distributed with a mean

of zero and a width approximating the detector's resolution. The residual distributions are constructed from the same selection of tracks that were used to perform the alignment, and are the focus of Section 4.2.2.1. A second check on the alignment involves observables sensitive to the track parameter resolution. In this case, cosmic rays are used, making use of a “split track” technique that takes advantage of the top-to-bottom cosmic ray trajectory (compared to the center-out trajectory of collision tracks). This method and the corresponding tests of the alignment are detailed in Section 4.2.2.2

Additionally, the effect of the beam spot constrained alignment on the impact parameter  $d_0$  needs to be checked. The  $d_0$  distributions for both the March and June alignments are compared to the MC simulation using a perfect geometry in Figure 4.4. In the March alignment, there is a bias of 18  $\mu\text{m}$  in the mean of the distribution and the width is nearly twice that of the perfect geometry. After the second pass of the June alignment, the mean has shifted to 1  $\mu\text{m}$  and the distribution has narrowed considerably. From this, it appears that the constrained alignment successfully removed the  $d_0$  bias.

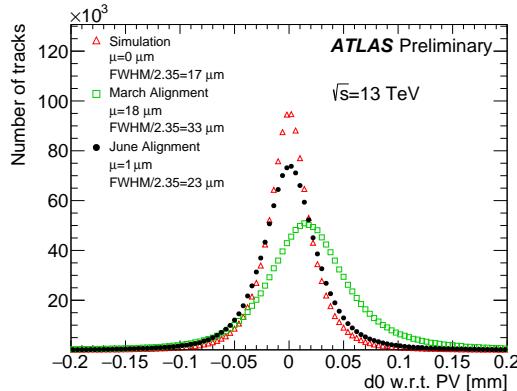

Figure 4.4: The  $d_0$  distributions with respect to the reconstructed primary vertex using the  $\sqrt{s} = 13 \text{ TeV}$  collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.

#### 4.2.2.1 Residual distributions from collisions

As mentioned previously, the primary focus of the June alignment campaign was on the IBL and the Pixel detectors. The detectors are the closest to the beam line and have the finest resolutions of the

715 ID subdetectors. The residual distributions in local  $x$  and  $y$  of the IBL planar sensors<sup>6</sup> are shown  
 716 in Figure 4.5. These and subsequent figures in this section compare the June and March alignments  
 717 to the perfectly-aligned MC simulation. Noticeable improvement in the distribution widths can be  
 718 seen in both the local  $x$ - and  $y$ -directions, nearly matching the simulation in local  $x$ , which is the  
 719 most sensitive direction.

720 Due to the temperature-dependent bowing of the IBL, it is also interesting to look at the means of  
 721 the residual distributions for each ring of IBL sensors along the beam line, as shown in Figure 4.6. A  
 722 deformation is clearly visible in the March alignment in both measurement directions, and the shape  
 723 in the local  $x$ -direction is consistent with an average stave bowing due to the different operating  
 724 temperature of the IBL during the March alignment and the 13 TeV collisions. This feature was  
 725 nearly eliminated in both directions through the L3 alignment of the IBL sensors.

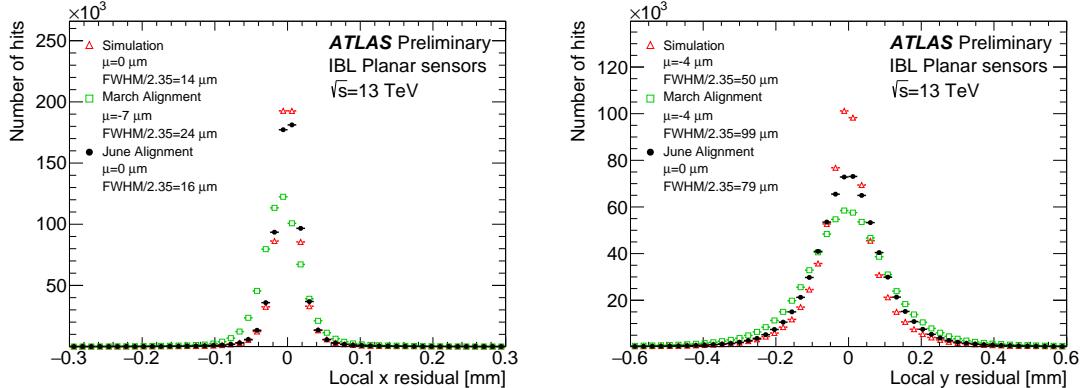

Figure 4.5: Local  $x$  (left) and local  $y$  (right) residual distributions of the IBL planar sensors using the  $\sqrt{s} = 13$  TeV collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.

726 The local  $x$  and  $y$  residual distributions for the Pixel detector barrel and end-caps are shown in  
 727 Figure 4.7. Even though the IBL is not included in the plots of the barrel, some of the noticeable  
 728 improvement in the more sensitive local  $x$  direction is an effect of the improved IBL alignment.  
 729 Similarly, the relatively broad local  $y$  residual distribution in the barrel likely indicates that further  
 730 refinement of the IBL alignment was needed along that direction. Even so, the June alignment  
 731 outperforms the March alignment and rivals the simulation in most of the plots.

---

<sup>6</sup>The IBL contains 12 planar sensors in the center of a stave, with four 3D sensors on either end. Only the planar sensors are shown here due to low statistics in the 3D sensors as well as poor MC modeling of these sensors.

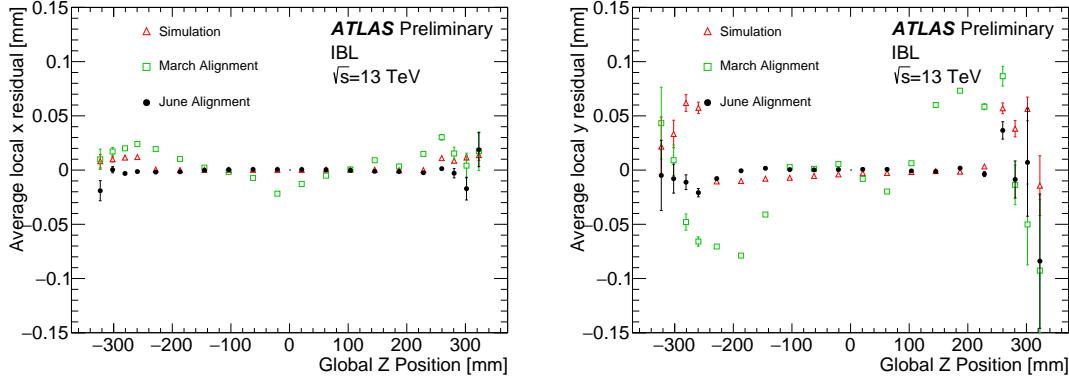

Figure 4.6: The mean of the local  $x$  (left) and local  $y$  (right) residual distributions as a function of the global  $z$  position of each IBL module using the  $\sqrt{s} = 13 \text{ TeV}$  collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red).

732     Similar distributions for the SCT and TRT barrel and end-caps are shown in Figures 4.8 and  
 733     4.9, respectively. Much like with the Pixel residuals, there is a reduction in the width of the TRT  
 734     residuals between the March and June alignments due to the alignment of the other subdetectors  
 735     improving the quality of the track fit. Even though neither subdetector was aligned at module-  
 736     level, the residuals indicate that the previous L3 alignment performed in Run 1 has not degraded  
 737     significantly during the upgrade and maintenance period.

#### 738     4.2.2.2 Track parameter resolution from cosmic rays

739     Cosmic ray data is very useful as an independent check on the alignment in the barrel of the  
 740     detector. While tracks from  $pp$  collisions originate within the detector and travel outwards, a cosmic  
 741     ray that passes through the center of the detector leaves a track in both halves of the detector.  
 742     If the cosmic ray is split in half, as in Figure 4.10, then it can be treated as two separate tracks  
 743     each with nearly identical track parameters (some differences arise due to energy loss as the particle  
 744     passes through the detector). The distribution of the difference in a given track parameter  $\Delta\tau$  is  
 745     approximately Gaussian with a variance  $\sigma^2(\Delta\tau)$ . Since both tracks come from the same particle,  
 746     each track individually has a variance equal to  $\sigma^2(\Delta\tau)/2$ . The resolution of the track parameter is  
 747     then given by the root mean square of the distribution divided by  $\sqrt{2}$ .

748     Cosmic rays whose split tracks each had transverse momentum  $p_T > 2 \text{ GeV}$  and at least one,  
 749     eight, and 25 hits in the barrels of the Pixel, SCT, and TRT detectors, respectively, were selected to

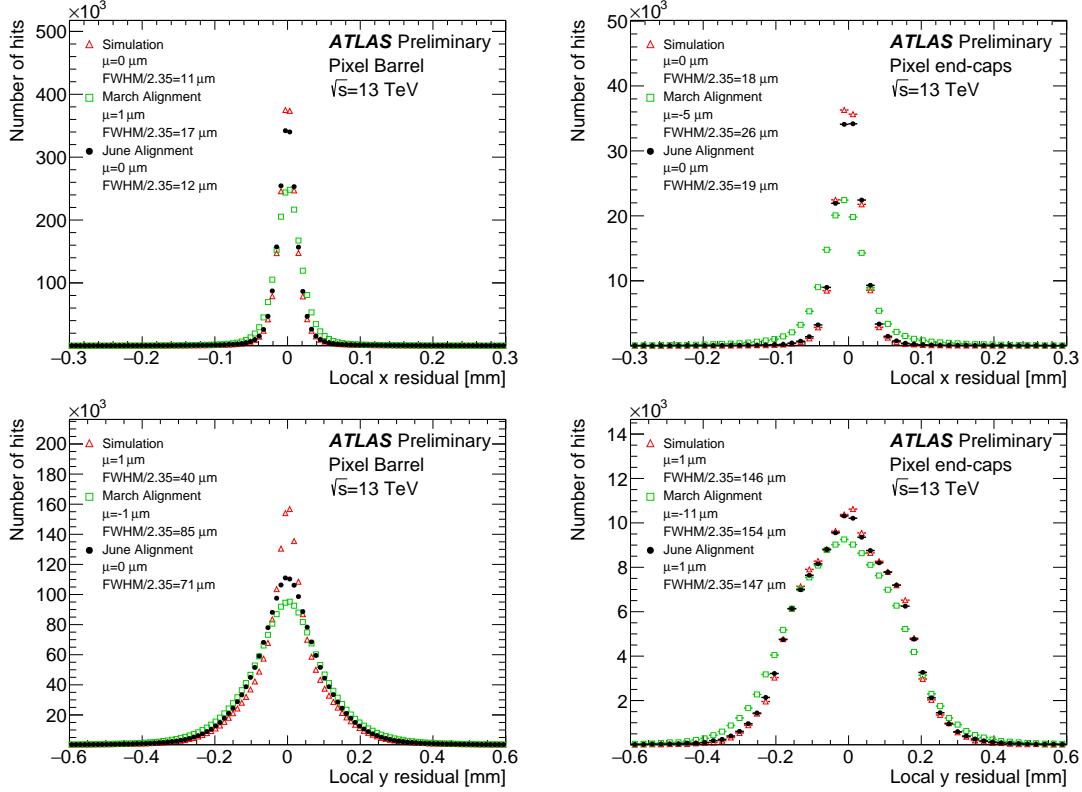

Figure 4.7: Local  $x$  (top) and local  $y$  (bottom) residual distributions for the Pixel barrel (excluding the IBL, left) and end-caps (right) using the  $\sqrt{s} = 13$  TeV collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.

measure a collection of track parameters. Figure 4.11 shows the difference in the impact parameter  $\Delta d_0$  and the charge divided by the transverse momentum  $\Delta q/p_T$  of the selected split-track cosmic rays for both the March and June alignments. Both distributions show a reduction in width in the June alignment, corresponding to an improvement in the resolution of each track parameter. The  $\Delta d_0$  plot shows a significant improvement in the June alignment, further validating the removal of the bias in the impact parameter.

### 4.2.3 Error scaling

The final step in preparing the new set of June alignment constants deals with the adjustment of the hit errors, or *error scaling*. Knowledge of the exact position of a hit measurement on a track

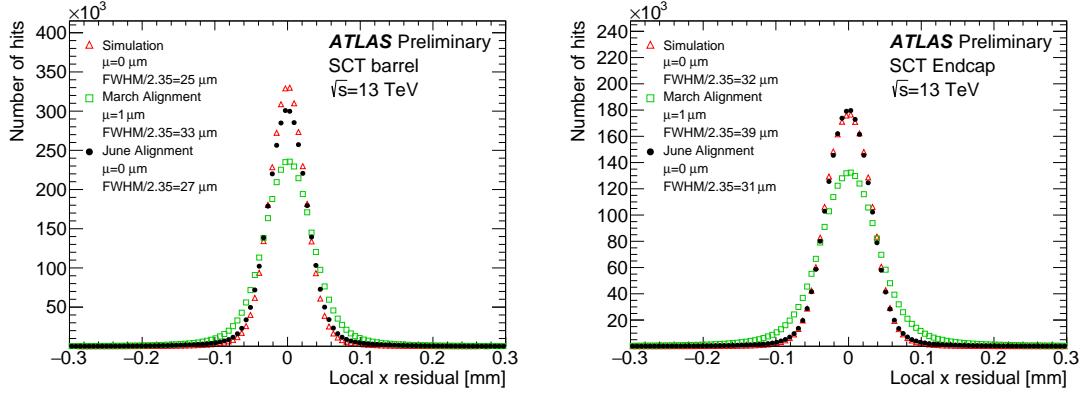

Figure 4.8: Local  $x$  residual distributions for the SCT barrel (left) and end-caps (right) using the  $\sqrt{s} = 13 \text{ TeV}$  collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.

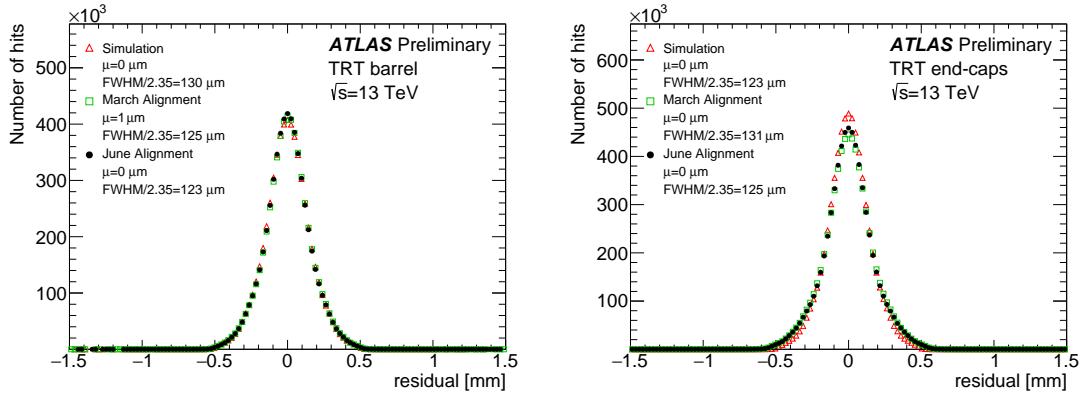

Figure 4.9: Residual distributions for the TRT barrel (left) and end-caps (right) using the  $\sqrt{s} = 13 \text{ TeV}$  collision data sample reconstructed using the June (black) and March (green) alignments. The data is compared to a MC simulation using a perfect detector geometry (red). The distributions are normalized to the same number of entries.

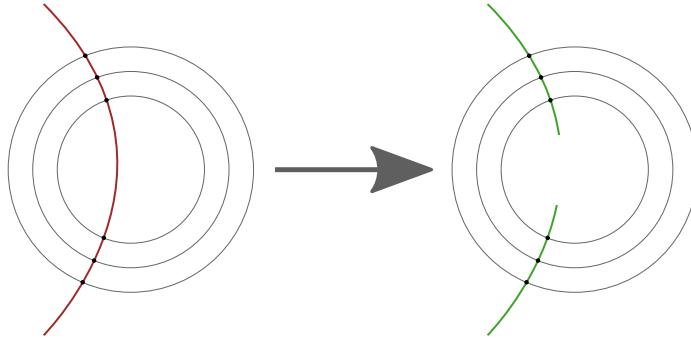

Figure 4.10: Representation of splitting a single cosmic ray track passing through the entire detector (left) into two separate tracks (right).

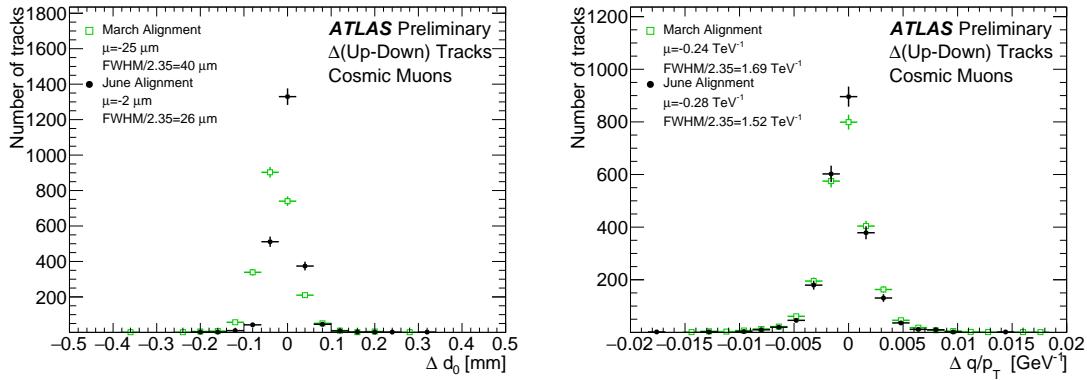

Figure 4.11: Distribution of the difference in the impact parameter  $\Delta d_0$  (left) and charge over transverse momentum  $\Delta q/p_T$  (right) between the two cosmic ray split tracks. The June (black) and March (green) alignments are compared. The distributions are normalized to the same number of entries.

is limited by the accuracy with which the sensors' positions are known. Let  $\sigma$  represent the hit uncertainty used in track fitting, and  $\sigma_0$  be the detector's intrinsic uncertainty. If  $\sigma = \sigma_0$ , the pull of the track-hit residual distributions should form a Gaussian distribution centered at zero with a standard deviation  $\sigma = 1$  [10]. In the case of residual misalignment, the pull distributions' standard deviations will stray from unity. The hit uncertainty can be written as:

$$\sigma = a \cdot \sigma_0 \oplus b \quad (4.12)$$

where  $a$  is a scaling factor, and  $b$  is a constant term which can be interpreted as a measure of any remaining misalignment of the detector elements. In this alignment campaign, the value of  $a$  is fixed at  $a = 1$  and  $b$  is evaluated from the residual pull distributions for each subdetector in its sensitive

767 directions.

768 Once the value of  $b$  is determined, pull distributions derived from the new value of  $\sigma$  should  
769 have unit width. The error scaling values for each subdetector are listed in Table 4.3, and the pull  
770 distributions for the IBL after error scaling are shown in Figure 4.12.

Detector	Coordinate	$b(\mu\text{m})$
IBL	$x$	6.4
	$y$	43.6
Pixel	$x$	5.2
	$y$	28.6
SCT	$x$	7.5
	$y$	0
TRT	$x$	10.8
	$r\phi$	0
Pixel	$x$	8.6
	$r\phi$	0

Table 4.3: Estimated value of the error scaling term  $b$  for each subdetector component with the June alignment.

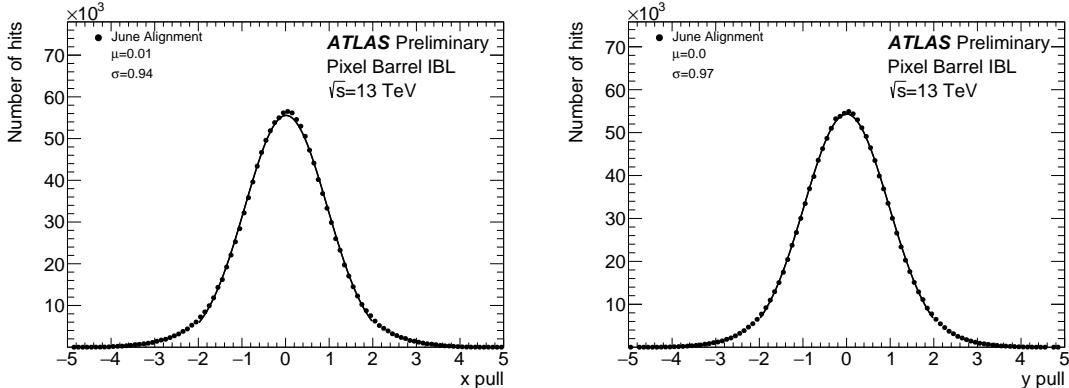

Figure 4.12: Pull distributions in local  $x$  (left) and  $y$  (right) for the IBL using the  $\sqrt{s} = 13$  TeV collision data sample after applying the error scaling.

### 771 4.3 Momentum bias from sagitta deformations

772 A variety of weak mode deformations can exist in the detector even after alignment. As mentioned  
773 previously, these weak modes consist of misalignments which don't affect the  $\chi^2$  of the residuals  
774 and thus are not handled by the basic alignment algorithm. In the presence of a weak mode, the  
775 description of the detector geometry can still provide efficient and high quality track fits, but there

may also be systematic biases in one or more track parameters. Several weak modes, their impacts on the reconstruction, and the steps taken to eliminate them are detailed in [13, 20]. This section focuses specifically on sagitta distortions that result in a bias in the reconstructed track momentum.

These *sagitta* distortions consist of detector movements orthogonal to the trajectory of the outgoing particle. The effect on the reconstructed track curvature is different for positively and negatively charged particles, resulting in a charge-antisymmetric bias. This effect is illustrated in the curl deformation shown in Figure 4.13.

In the plane transverse to ATLAS’s magnetic field, outgoing particle tracks form circular arcs. The sagitta is defined as the distance from the center of this arc to the center of its base, as shown in Figure 4.14, and it represents the “amount of bending” in the track. In the case where the sagitta  $s$  is considerably smaller than the detector radius  $R_0$ , which is a valid assumption when working with high momentum tracks, the transverse momentum of a particle of charge  $q$  can be written as [21]:

$$p_T \propto qB \frac{R_0^2}{8s} \quad (4.13)$$

where  $B$  is the strength of the detector’s magnetic field. If a sagitta bias is present, the track’s transverse momentum shifts by [20]:

$$q/p_T \rightarrow q/p_T + \delta_s \quad \text{or} \quad p_T \rightarrow p_T \cdot (1 + qp_T\delta_s)^{-1} \quad (4.14)$$

where  $\delta_s$  is a universal bias parameter that uniquely defines the deformation. Finally, since the reconstructed polar angle does not change under a sagitta deformation, the longitudinal component of the momentum scales along with the transverse component, and an equivalent equation can be written for the total momentum:

$$p \rightarrow p \cdot (1 + qp_T\delta_s)^{-1} \quad (4.15)$$

### 4.3.1 Sagitta bias monitoring with electron $E/p$

Since a sagitta bias results in changes in the momentum of particles’ tracks as measured by the ID, they can be identified using independent measurements from other systems in the detector. One such method involves using the energy-momentum ratio of electrons ( $E/p$ ). Since the electron’s energy is measured in ATLAS’s calorimeter systems, it is not sensitive to any sagitta bias that may exist in the ID and the corresponding track momentum. Under the assumption that the calorimeter response is independent of the charge of incoming particles, a charge-dependent momentum bias in the ID will manifest as a difference in the  $E/p$  ratio for electrons and positrons.

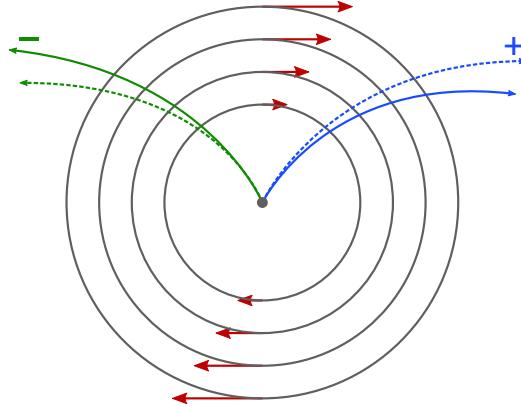

Figure 4.13: Representation of a curl distortion in the detector. The image shows a cutaway in the transverse plane. The deformation is represented by the red arrows, and the impact on the reconstructed positive (blue) and negative (green) tracks are shown. The dashed lines represent the true particle trajectories, and the solid lines represent the reconstructed trajectories.

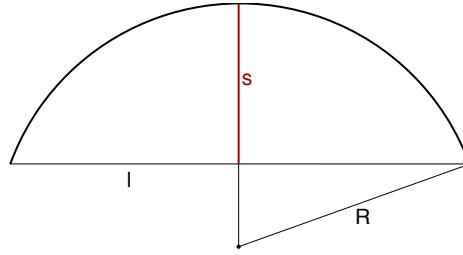

Figure 4.14: Geometric definition of the sagitta  $s$  in relation to the length of the chord  $l$  and the radius  $r$  of a circular arc.

802 In the presence of a sagitta bias, the momentum will change according to Equation 4.15 and the  
803 average measured  $\langle E/p \rangle$  can be written as:

$$\langle E/p \rangle^\pm \rightarrow \langle E/p \rangle^\pm \pm \langle E_T \rangle \delta_s \quad (4.16)$$

804 where the approximation  $p_T \approx E_T$  is used. Assuming that  $\langle E/p \rangle^+ = \langle E/p \rangle^-$  in the absence of a  
805 bias, the sagitta bias parameter can be written as:

$$\delta_s = \frac{\langle E/p \rangle^+ - \langle E/p \rangle^-}{2\langle E_T \rangle} \quad (4.17)$$

806 If the kinematic selections for electrons and positrons are identical, the energy scale of the calorimeter  
807 will not factor into the  $\langle E/p \rangle$  difference; however, it will affect  $\langle E_T \rangle$  which would scale the measured  
808  $\delta_s$ . This is expected to be a small effect, as the energy scale for electrons has been measured at  
809  $\sqrt{s} = 13$  TeV with uncertainties on the per-mil level across the entire detector [22].

810    **4.3.1.1 Measuring  $\langle E/p \rangle$**

811    The  $E/p$  ratio is measured using electrons and positrons from  $Z \rightarrow e^\pm e^\mp$  events in order to obtain  
 812    a high purity sample of electron candidates. They are required to pass a basic selection criteria to  
 813    ensure they are well measured by both the ID and the calorimeters:

- 814       •  $E_T > 25$  GeV
- 815       •  $|\eta| < 2.47$ , excluding the calorimeter’s barrel-to-endcap transition region in  $1.37 < |\eta| < 1.52$
- 816       • Pass **MediumLH** identification working point detailed in Section 3.2.4.3
- 817       • Pass a selection of quality cuts, including a requirement that the electron be identified using  
 818       cluster information in the calorimeter
- 819       • The associated track must have at least one hit in the IBL, three in the Pixel detector, and  
 820       five in the SCT detector.

821    Events with exactly two opposite-charge electrons passing this selection with a dielectron invariant  
 822    mass within 30 GeV of the  $Z$  boson mass are then used for the  $E/p$  calculation.

823    Since the size of the sagitta bias  $\delta_s$  is not expected to be constant across the entire detector,  
 824    a two-dimensional rectangular grid binned in detector  $\eta$  and  $\phi$  is constructed. From the selected  
 825    events, separate distributions of  $E/p$  are made for electrons and positrons lying in each bin. Each  
 826    distribution is fit with Crystal Ball function<sup>7</sup>, and the peak of the distribution is taken as the value  
 827    of  $\langle E/p \rangle$ . If there is no bias on the track momentum in the bin, the peaks for electrons and positrons  
 828    should match. Example  $E/p$  distributions including the Crystal Ball fits are shown in Figure 4.15.

829    It is important to emphasize that deviations from one in the *ratio* of  $\langle E/p \rangle$  for electrons and  
 830    positrons indicates that a momentum bias may be present. The value of  $\langle E/p \rangle$  itself is not expected  
 831    to equal one exactly, as the track momentum on average tends to be slightly lower than the energy  
 832    measurement in the calorimeter. This is due to the fact that if the electron were to radiate a photon,  
 833    its momentum would change slightly, while it is likely that both the electron and the emitted photon  
 834    would leave energy deposits near each other in the calorimeter and be reconstructed into the same  
 835    object.

836    Once the  $\langle E/p \rangle^\pm$  distributions in each  $\eta\phi$  bin have been extracted from the fits, a two dimensional  
 837    map of  $\delta_s$  can be constructed using Equation 4.17. The map gives an overview of sagitta  
 838    biases that may be present in the detector, and can be used by the alignment algorithm to reduce

---

<sup>7</sup>The Crystal Ball function is a probability density function consisting of a Gaussian core and a power-law tail.

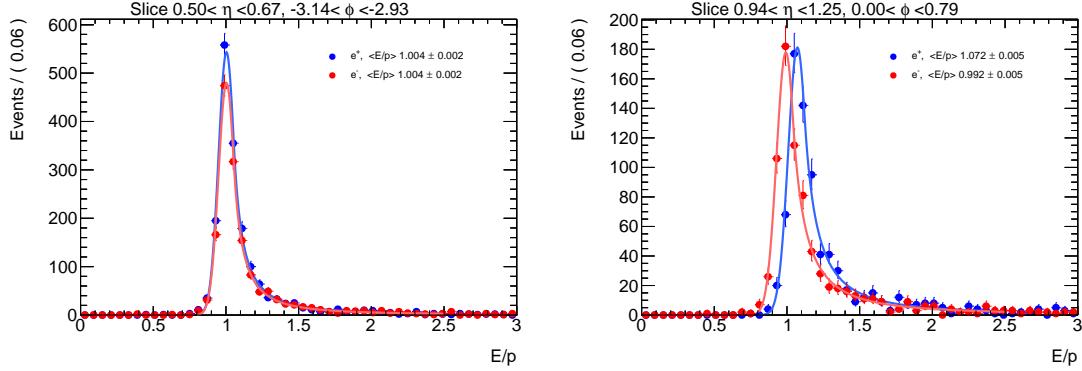

Figure 4.15:  $E/p$  distributions of electrons and positrons in two different  $\eta\phi$  bins of the detector. The left hand plot is taken from a region with no momentum bias where  $\langle E/p \rangle^+ = \langle E/p \rangle^-$ , while the right hand plot shows an 8% disagreement in  $\langle E/p \rangle$  between electrons and positrons.

839 the bias in the next iteration. In this case, the tracks fed to the alignment have their momenta  
840 corrected according to [20]:

$$q/p_{\text{corr}} = q/p_{\text{reco}}(1 - qp_T\delta_s) \quad (4.18)$$

841 where  $p_{\text{reco}}$  is the reconstructed momentum of the track. The corrected momentum is then con-  
842 strained in the alignment.

#### 843 4.3.1.2 Results in 13 TeV data

844 The  $E/p$  method has been used to monitor sagitta biases in the detector several times over the  
845 course of Run 2. During this time, it has primarily served as an independent cross-check to a  
846 second method using  $Z \rightarrow \mu^\pm \mu^\mp$  events [20]. The  $Z \rightarrow \mu^\pm \mu^\mp$  method identifies individual track  
847 momentum biases through shifts in the reconstructed  $Z$  mass, which leaves it relatively insensitive  
848 to global sagitta biases. For this reason, the sagitta bias maps produced using this technique are  
849 normalized to those from the  $E/p$  method before being used to constrain the alignment.

850 The results of two implementations of the  $E/p$  method are presented here.

- 851 1. The first follows the end-of-year reprocessing of the entire ATLAS 2016 data set at  $\sqrt{s} = 13$  TeV.  
852 Two sets of alignment constants are compared: the *prompt* alignment, which was derived  
853 shortly after each run was recorded, and the *reprocessed* alignment. The maps of the sagitta  
854 bias comparing the two alignments calculated using the  $E/p$  method are shown in Figure 4.16,  
855 and the comparison of the  $\eta$  projection of each map is shown in Figure 4.17.

856     2. The second uses the 2017 data after reprocessing, and compares the effects of multiple it-  
 857     erations of the method. In each iteration, the momenta of the electrons and positrons are  
 858     corrected based on Equation 4.15 using the value of  $\delta_s$  computed in the previous iteration,  
 859     and a new sagitta bias map is calculated. If the method is indeed characterizing the sagitta  
 860     biases correctly, the corrections should converge quickly. The initial sagitta bias map is com-  
 861     pared to the map after two such iterations in Figure 4.18, and the sagitta bias projected along  
 862      $\eta$  for each iteration is shown in Figure 4.19. Indeed, after just two iterations,  $\delta_s$  is consistent  
 863     with zero in nearly all bins.

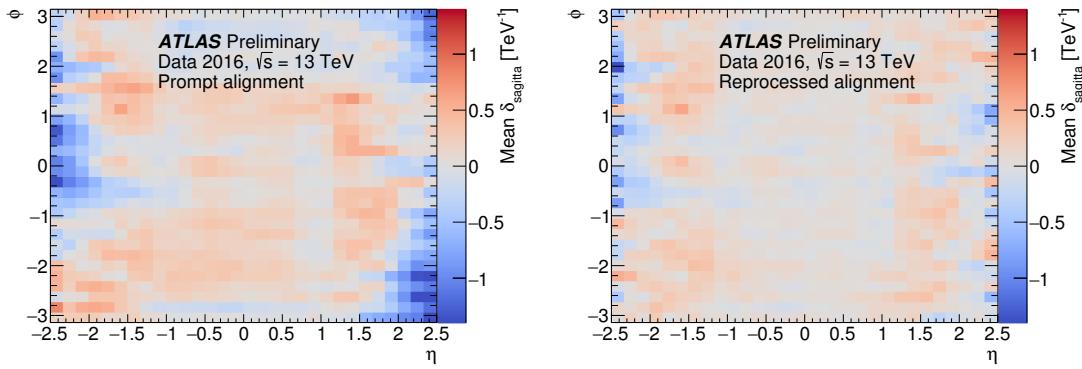

Figure 4.16: Sagitta bias in the  $\sqrt{s} = 13$  TeV data collected by ATLAS in 2016 as a function of  $\eta$  and  $\phi$  for the prompt (left) and reprocessed (right) alignments using the  $E/p$  method.

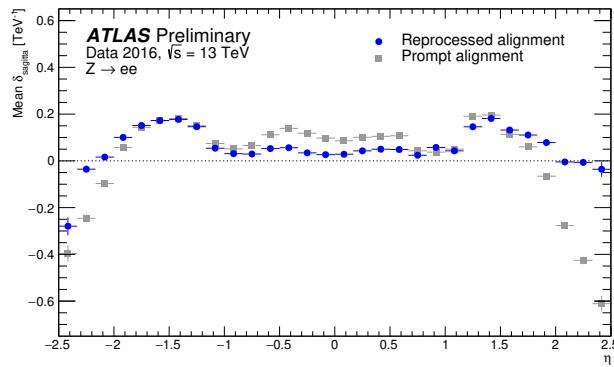

Figure 4.17: Sagitta bias in the  $\sqrt{s} = 13$  TeV data collected by ATLAS in 2016 projected along  $\eta$  for the prompt (gray) and reprocessed (blue) alignments using the  $E/p$  method.

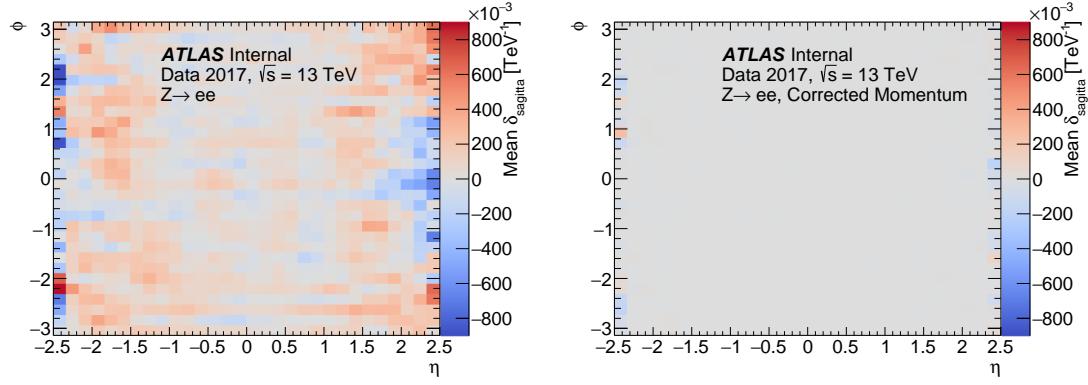

Figure 4.18: Sagitta bias in the  $\sqrt{s} = 13 \text{ TeV}$  data collected by ATLAS in 2017 as a function of  $\eta$  and  $\phi$  in reconstructed electrons (left) and after two iterations of momentum corrections (right) from the  $E/p$  method.

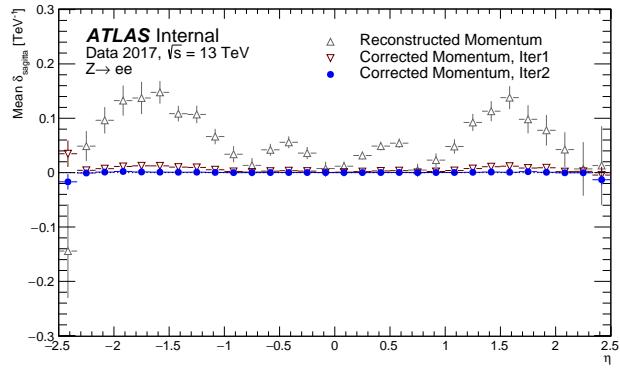

Figure 4.19: Sagitta bias in the  $\sqrt{s} = 13 \text{ TeV}$  data collected by ATLAS in 2017 projected along  $\eta$  in reconstructed electrons (gray) and after one (red) and two (blue) iterations of momentum corrections from the  $E/p$  method.

## CHAPTER 5

---

865

866

# Measurement of same-sign $WW$ production at $\sqrt{s} = 13$ TeV with ATLAS

---

867 Production of same-sign  $W$  boson pairs is a particularly interesting SM process. When produced  
 868 via vector boson scattering (VBS),  $W^\pm W^\pm jj$  is particularly sensitive to the electroweak symmetry  
 869 breaking (EWSB) mechanism as well as potential “beyond the Standard Model” (BSM) physics.  
 870  $W^\pm W^\pm jj$  events can be produced via electroweak-mediated (EWK) diagrams, of which VBS is a  
 871 subset, or QCD-mediated diagrams. The biggest advantage of same-sign  $W^\pm W^\pm jj$  lies in its ratio  
 872 of electroweak (EWK) to QCD production cross sections. Despite the opposite-sign  $W^\pm W^\mp$  having  
 873 a considerably larger total cross section, its EWK-mediated diagrams are considerably smaller than  
 874 its QCD-mediated diagrams, while for same-sign  $W^\pm W^\pm$  the ratio is approximately one to one.  
 875 This makes  $W^\pm W^\pm jj$  one of the best channels for studying VBS at the LHC.

876 The first evidence of electroweak (EWK)  $W^\pm W^\pm jj$  production was seen by the ATLAS and  
 877 CMS experiments at  $\sqrt{s} = 8$  TeV with excesses of  $3.6\sigma$  [23] and  $2.0\sigma$  [24] over backgrounds,  
 878 respectively. More recently, ATLAS and CMS have both observed the EWK process at  $\sqrt{s} = 13$  TeV  
 879 with significances of  $6.9\sigma$  [2] and  $5.5\sigma$  [25], respectively. The analysis presented in this chapter  
 880 is based off of the ATLAS  $\sqrt{s} = 13$  TeV observation and cross section measurement of EWK  
 881  $W^\pm W^\pm jj$  production [2, 26].

### 882 5.0.2 Theoretical overview of vector boson scattering

883 VBS processes are very important to understand due to their sensitivity to the EWSB mechanism.  
 884 The scattering amplitude of longitudinally polarized vector bosons grows with center-of-mass energy  
 885 and ultimately violates unitarity above  $\sqrt{s} = 1$  TeV in the absence of a light SM Higgs boson [27],

286 [28]. However, once the Higgs is introduced, the divergences cancel and the cross section no longer  
 287 grows unbounded, as can be seen in Figure 5.1, which consists of plots from [29].

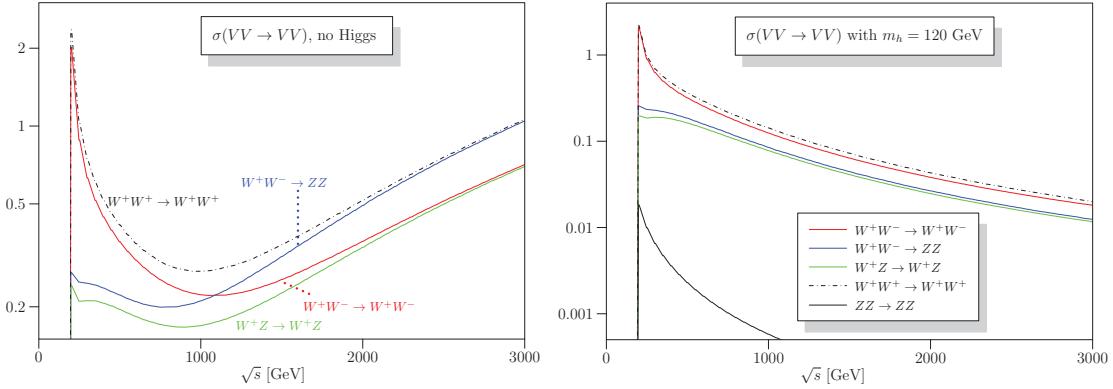

Figure 5.1: Cross sections in nanobarns for five different scattering processes of longitudinally polarized vector bosons as a function of center of mass energy  $\sqrt{s}$ . Without a SM Higgs boson (left), the cross sections grow unbounded with  $\sqrt{s}$ ; however with a 120 GeV Higgs boson (right), the cross sections no longer diverge. Plots taken from [29].

888 With the discovery of the Higgs boson in 2012 [30, 31], the EWSB mechanism can now be directly  
 889 studied. Due to the exchange of a Higgs in the  $s$ - and  $t$ -channel VBS diagrams ( $W^\pm W^\pm jj$  itself only  
 890 contains the  $t$ -channel diagram), VBS processes are directly sensitive to properties of the Higgs. For  
 891 example, the high-mass tail in the  $VV$  scattering system allows an approximation of the effective  
 892 coupling strength of the Higgs to vector bosons that is independent of any assumptions on the Higgs  
 893 width [32]. Additionally, the center of mass energy dependence of the  $VV$  scattering can reveal  
 894 whether the Higgs boson unitarizes the longitudinal scattering amplitude fully or only partially [33].

895 VBS events are characterized by two quarks from the colliding protons each radiating a massive  
 896 vector boson which then scatter and decay in the detector. The incoming quarks carry a large  
 897 amount of momentum and only deflect a small amount upon radiating the vector boson; as a result,  
 898 they often travel very close to the beam line. Ignoring the decay products of the bosons, these VBS  
 899 events result in a final state of two vector bosons ( $V$ ) and two jets ( $j$ ) at high pseudorapidities  
 900 (called *forward jets*) from the outgoing quarks. The shorthand  $VVjj$  is used to represent this final  
 901 state.

902  $VVjj$  events can be produced via two different physical processes. The first involves purely  
 903 electroweak interactions in the tree-level diagrams, with  $\mathcal{O}(\alpha_{EWK}) = 6$  and will be referred to as  
 904 *EWK production*. This can be further broken down into VBS and non-VBS production. In the  
 905 VBS EWK production, the scattering occurs via triple or quartic gauge couplings, as well as the

906  $s$ - or  $t$ -channel exchange of a Higgs boson. The non-VBS EWK production contains the same final  
 907 state of two vector bosons and two outgoing quarks, but the bosons do not scatter. Due to gauge  
 908 invariance, it is not possible to separate the VBS from the non-VBS productions [34]; therefore,  
 909 both are included in the signal generation and are indistinguishable from one another. The second  
 910 process involves a mix of the EWK and strong interactions, of order  $\mathcal{O}(\alpha_s) = 2 \otimes \mathcal{O}(\alpha_{\text{EWK}}) = 4$  and  
 911 will be referred to as *QCD production*. The tree-level Feynman diagrams for VBS EWK, non-VBS  
 912 EWK, and QCD  $VVjj$  production are found in Figures 5.2, 5.3, and 5.4, respectively.

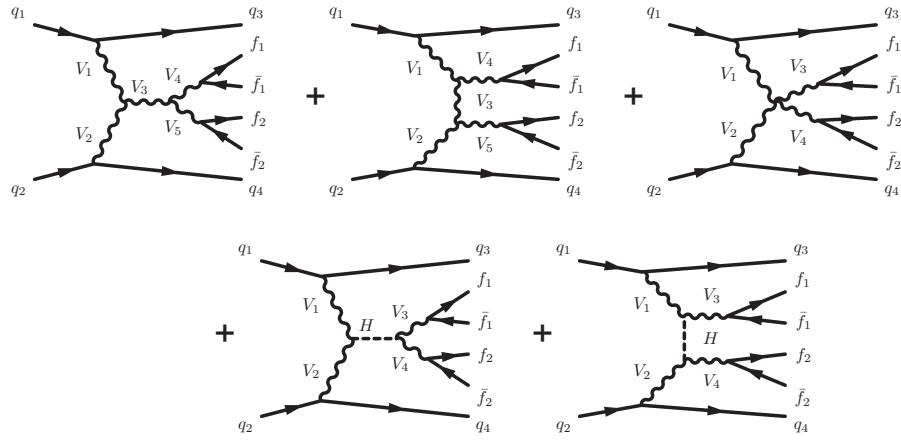

Figure 5.2: Tree-level Feynman diagrams for VBS EWK  $VVjj$  production including triple gauge couplings involving  $W$  and/or  $Z$  bosons (top left and top middle), quartic gauge coupling (top right), or the exchange of a Higgs boson ( $s$ -channel bottom left and  $t$ -channel bottom right). The labels are quarks ( $q$ ), fermions ( $f$ ), and gauge bosons ( $V = W, Z$ ).

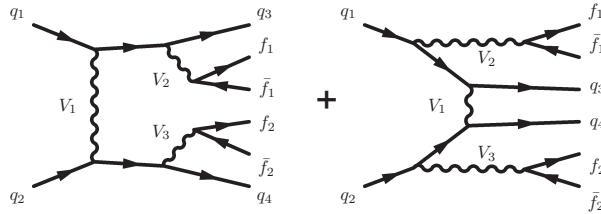

Figure 5.3: Tree-level Feynman diagrams for non-VBS EWK  $VVjj$  production. The labels are quarks ( $q$ ), fermions ( $f$ ), and gauge bosons ( $V = W, Z$ ).

### 913 5.0.3 Same-sign $W^\pm W^\pm$ scattering

914 Same-sign  $W^\pm W^\pm jj$  scattering is considered to be one of the best channels for studying VBS at the  
 915 LHC [32]. This is due primarily to the ratio of the EWK to the QCD production, which matters

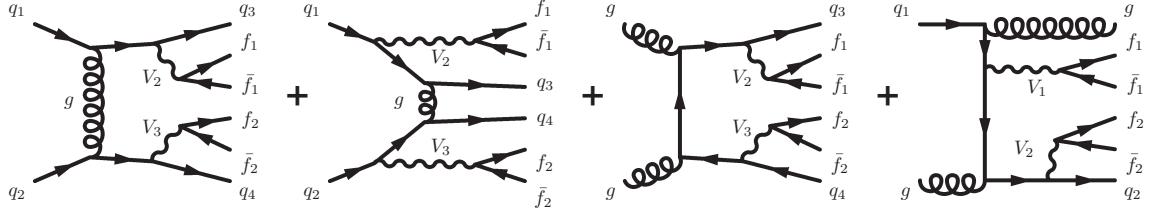

Figure 5.4: Tree-level Feynman diagrams for QCD  $VVjj$  production. The labels are quarks ( $q$ ), fermions ( $f$ ), and gauge bosons ( $V = W, Z$ ).

916 a great deal due to the VBS events being a subset of the total EWK production. In an analysis  
 917 the EWK production would be considered the signal and the QCD production a background, so a  
 918 favorable ratio of the two helps greatly when comparing the size of the signal to the backgrounds.  
 919 A study at  $\sqrt{s} = 8$  TeV [35] was done using the **SHERPA** Monte Carlo (MC) generator to calculate  
 920 EWK and QCD production cross sections at leading order for a variety of  $VVjj$  processes decaying  
 921 to leptons and can be found in Table 5.1. Despite its lower cross section compared to other  $VVjj$   
 922 processes, the EWK to QCD ratio for  $W^\pm W^\pm jj$  is approximately one-to-one, whereas for opposite-  
 923 sign  $W^\pm W^\mp jj$  the ratio is closer to 3%.

Process	Final state	$\sigma_{\text{EWK}}$	$\sigma_{\text{QCD}}$
$W^\pm W^\pm$	$l^\pm l^\pm \nu\nu jj$	19.5 fb	18.8 fb
$W^\pm W^\mp$	$l^\pm l^\mp \nu\nu jj$	91.3 fb	3030 fb
$W^\pm Z$	$l^\pm l^\pm l^\mp \nu jj$	30.2 fb	687 fb
$ZZ$	$l^+ l^- \nu\nu jj$	2.4 fb	162 fb
$ZZ$	$l^+ l^- l^+ l^- jj$	1.5 fb	106 fb

Table 5.1: Predicted cross sections for EQK and QCD production of diboson processes relevant to VBS at  $\sqrt{s} = 8$  TeV using the **SHERPA** MC generator. Loose generator level cuts are applied on lepton  $p_T > 5$  GeV, dilepton invariant mass  $m_{ll} > 4$  GeV, and at least two jets with  $m_{jj} > 10$  GeV. Numbers taken from [35].

924 This analysis studies  $W^\pm W^\pm jj$  scattering where both  $W$  bosons decay leptonically to  $e\nu$  or  $\mu\nu$ <sup>8</sup>.  
 925 The  $W^\pm W^\pm jj$  VBS final state consists of two leptons with the same electric charge, two neutrinos,  
 926 and two high energy forward jets with a large invariant mass. Tree-level Feynman diagrams of VBS  
 927  $W^\pm W^\pm jj$  production can be found in Figure 5.5 and a visual representation of the VBS topology  
 928 can be found in Figure 5.6. The two forward jets also serve as a powerful tool to suppress the  
 929 QCD production mode. In EWK events, the two jets tend to have much higher separation and a  
 930 larger combined invariant mass than the two leading jets in a QCD event. The two plots shown in

<sup>8</sup>Throughout the rest of this chapter,  $l$  denotes either electrons ( $e$ ) or muons ( $\mu$ ) unless stated otherwise. Additionally,  $e$ ,  $\mu$ , and  $\nu$  (neutrino) with no charge or anti-particle designation refer interchangeably to either the particle or anti-particle.

931 Figure 5.7 highlight the differences in these dijet quantities between the two production modes. An  
 932 ATLAS event display of a real  $W^\pm W^\pm jj$  candidate event is shown in Figure 5.8.

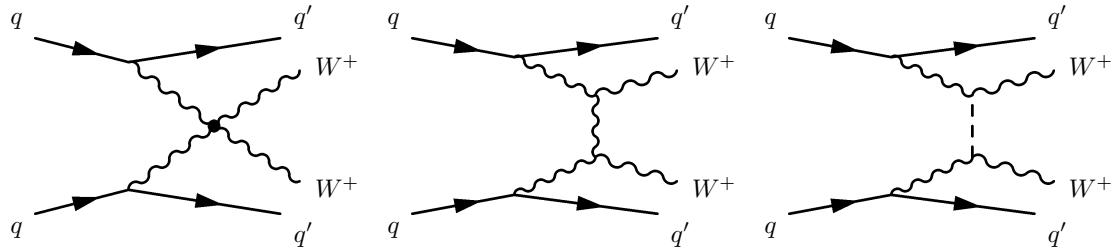

Figure 5.5: Feynman diagrams for VBS EWK production of  $W^\pm W^\pm jj$  events. The leftmost diagram contains a quartic gauge coupling vertex, and the rightmost diagram contains an exchange of a Higgs boson. **TODO: Make diagrams consistent with others**

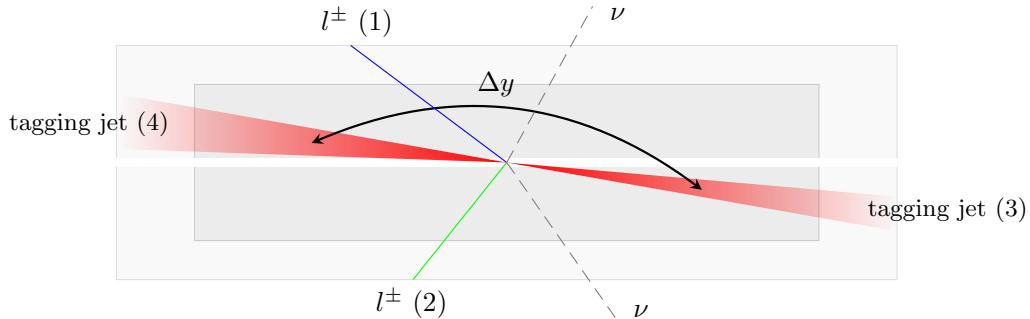

Figure 5.6:  $W^\pm W^\pm jj$  VBS event topology containing two leptons (1 and 2) with the same electric charge, two neutrinos, and two forward tagging jets (3 and 4) with large rapidity separation  $\Delta y$ .

#### 933 5.0.4 Overview of backgrounds

934 In addition to QCD production of  $W^\pm W^\pm jj$  events, there are several other processes that can end  
 935 up with a final state of two same-sign leptons, two neutrinos, and two jets. However, due to the ±2  
 936 final state charge, there is a considerable reduction in SM backgrounds (such as  $Z$  boson events)  
 937 when compared to an analysis like opposite-sign  $W^\pm W^\mp jj$ .

938 One of the largest sources of background involves processes with prompt leptons<sup>9</sup>. These are  
 939 events that contain two leptons with the same electric charge and one or more additional leptons

<sup>9</sup>Prompt leptons are those that are produced in the primary collision and are a direct decay product of the process of interest. Non-prompt leptons originate from some secondary process, such as a  $b$ -hadron decay, or are jets that get mis-reconstructed as a lepton.

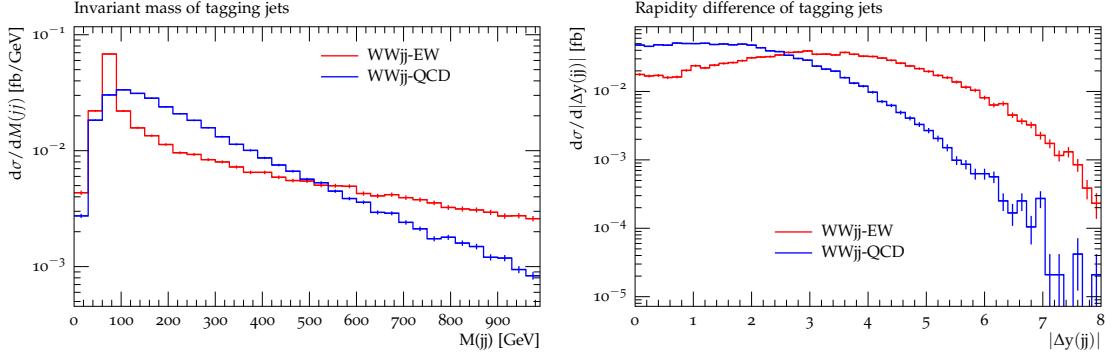

Figure 5.7: Generator level comparisons at  $\sqrt{s} = 8$  TeV of dijet invariant mass ( $m_{jj}$ , left) and dijet rapidity ( $\Delta y_{jj}$ , right) in EWK (red) and QCD (blue)  $W^\pm W^\pm jj$  events. Both data sets have been normalized to the same area. Plots taken from [35].

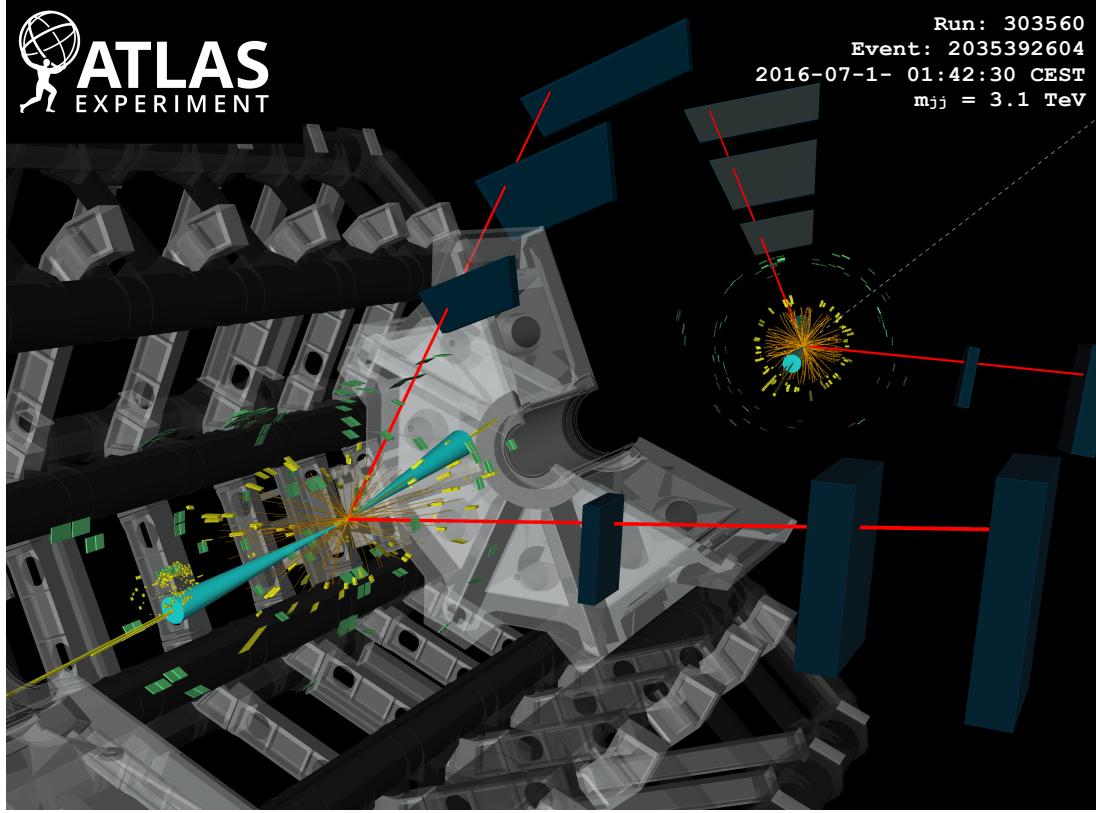

Figure 5.8: ATLAS event display of a  $pp \rightarrow W^+ W^+ \rightarrow \mu^+ \nu_\mu \mu^+ \nu_\mu jj$  event. The muons are represented by the red lines travelling from the ID through the MS, and the forward jets are represented by the blue cones with yellow energy deposits in the calorimeters. The direction of the  $E_T^{\text{miss}}$  in the transverse plane is indicated by the gray dashed line in the inset image. Event display taken from [2].

940 that are “lost”, either by failing the selection criteria or falling outside of the detector’s acceptance.  
 941 The number of processes that can contribute is limited by the requirement of same-sign leptons, and  
 942 as a result this background is dominated by processes involving two or more vector bosons, with the  
 943 largest contribution coming from  $WZ$  events and smaller contributions from  $ZZ$  and  $t\bar{t}V$  events.  
 944 Triboson events where one boson decays hadronically also contribute to this background; however,  
 945 the jets are generally softer and more central than in a typical VBS event, and the cuts applied on  
 946 the forward jets suppress these contributions.

947 The other dominant background comes from non-prompt, or “fake”, leptons. Here one or more  
 948 leptons originate from the decay of another particle unrelated to the signal process, such as a  
 949 heavy-flavor decay or photon conversion, or come from a jet that is misidentified as a lepton. This  
 950 background is mostly made up of events from  $t\bar{t}$  and  $W+\text{jets}$  processes, with a much smaller contribu-  
 951 tion from  $V\gamma$  events. **TODO: check whether  $V\gamma$  really qualifies as non-prompt, we lump  $Z\gamma$  in**  
 952 **with the charge flip background in the paper...**

953 Finally, opposite-sign lepton pairs can enter the signal region if one of the leptons is reconstructed  
 954 with the wrong charge (called *charge misidentification*<sup>10</sup>). In practice, this only affects events with  
 955 electrons, as the charge misidentification rate for muons is negligible [36]. This is a major background  
 956 in events with two electrons, but is a much smaller contribution for events with one electron and  
 957 one muon.

## 958 5.1 Data and Monte Carlo samples

959 This analysis uses  $36.1 \text{ fb}^{-1}$  of  $\sqrt{s} = 13$  TeV proton-proton collision data recorded by ATLAS  
 960 during 2015 and 2016. The uncertainty in the combined integrated luminosity is 2.1%. It is derived  
 961 following a methodology similar to that detailed in [37] and using the LUCID-2 detector for the  
 962 baseline luminosity measurements [38] from calibration of the luminosity scale using  $x$ - $y$  beam-  
 963 separation scans.

### 964 5.1.1 Monte Carlo samples

965 A number of Monte Carlo (MC) simulations are employed to model signal and background pro-  
 966 cesses. In order to model the real collision data as closely as possible, each MC has been run through  
 967 a full simulation of the ATLAS detector [39] in GEANT4 [40], and events have been reconstructed

---

<sup>10</sup>Charge misidentification is also referred to interchangeably as *charge mis-ID* and *charge flip*.

968 using the same algorithms as the data. The simulation reproduces as closely as possible the momentum  
 969 resolutions and calorimeter responses of the detector, and also includes the effects of pileup by  
 970 including soft QCD interactions using PYTHIA v8.1 [41]. The MC samples used in this analysis are  
 971 detailed in this section and summarized in Table 5.2.

972 The  $W^\pm W^\pm jj$  samples are modeled using SHERPA v2.2.2 [42, 43, 44] with the NNPDF3.0 PDF  
 973 set [45]. The EWK signal samples are generated by fixing the electroweak coupling constant to  
 974  $\mathcal{O}(\alpha_W) = 6$ , and a QCD background sample was also generated with  $\mathcal{O}(\alpha_W) = 4$ . SHERPA includes  
 975 up to one parton at next-to-leading order (NLO) and up to three at leading order (LO) in the  
 976 strong coupling constant  $\alpha_s$ . A second  $W^\pm W^\pm jj$  EWK sample is generated using POWHEG-BOX  
 977 v2 [46] with the NNPDF3.0 PDF set and at NLO accuracy. This sample is only used for systematic  
 978 studies, as POWHEG-BOX does not include resonant triboson contributions in its matrix element, which  
 979 are non-negligible at NLO [47].

980 Diboson processes ( $VV$  where  $V = W, Z$ ) are simulated with SHERPA v2.2.2 for mixed hadronic  
 981 and leptonic decays and SHERPA v2.2.1 for fully leptonic decays of the bosons. Similarly, triboson  
 982 ( $VVV$ ) and  $V\gamma$  processes are simulated using SHERPA v2.1.1 with up to one parton at NLO and up  
 983 to three at LO.  $W+jets$  processes are simulated with SHERPA2.2.1 with up to two partons at NLO  
 984 and four at LO. All the above SHERPA samples use the NNPDF3.0 PDF set and SHERPA's own parton  
 985 showering. The  $Z+jets$  events are generated with Madgraph5\_aMC@NLO [48] at LO and interfaced  
 986 with PYTHIA v8.1 for parton showering.

987  $t\bar{t}$  events are generated using POWHEG-BOX v2 with the CT10 PDF set [49].  $t\bar{t}V$  samples are  
 988 generated at NLO with Madgraph5\_aMC@NLO and the NNPDF3.0 PDF set interfaced with PYTHIA v8  
 989 for parton showering. Finally, single top events are generated with POWHEG-BOX v1 and the CT10f4  
 990 PDF set interfaced with PYTHIA v6 [50] for parton showering.

## 991 5.2 Object and event selection

992 This section details the selection criteria for objects used in the analysis as well as the selection for  
 993 signal events.

### 994 5.2.1 Object selection

995 Muons, electrons, and jets all must pass strict selection requirements to ensure that only high quality,  
 996 well measured objects are used. For leptons, a baseline selection is defined (called the *preselection*),  
 997 which all leptons must pass in order to be considered for the analysis. This preselection is an

Process	Generator	Comments
$W^\pm W^\pm jj$ (EWK)	SHERPA v2.2.2	Signal sample
$W^\pm W^\pm jj$ (EWK)	POWHEG-BOX v2	Systematics sample
$W^\pm W^\pm jj$ (QCD)	SHERPA v2.2.2	
Diboson	SHERPA v2.2.2	Both bosons decay leptonically ( $llll$ , $lll\nu$ , $ll\nu\nu$ )
Triboson	SHERPA v2.2.1	One boson decays leptonically, the other hadronically
$W + \text{jets}$	SHERPA v2.2.1	
$Z + \text{jets}$	Madgraph5_aMC@NLO	
$V\gamma$	SHERPA v2.1.1	
$V\gamma jj$ (EWK)	SHERPA v2.2.4	
$t\bar{t}V$	Madgraph5_aMC@NLO	
$t\bar{t}$	POWHEG-BOX v2	
Single top	POWHEG-BOX v1	EWK $t$ -, $s$ -, & $Wt$ -channels

Table 5.2: Summary of MC samples used in the analysis.

998 intentionally loose set of criteria in order to have high acceptance for rejecting backgrounds with  
 999 additional leptons (i.e.  $WZ \rightarrow 3l\nu jj$ ). Signal leptons are then required to satisfy a much tighter  
 1000 *signal selection* aimed at suppressing backgrounds from non-prompt or fake leptons. A third set of  
 1001 lepton selection criteria, the *loose selection*, defines a sample enriched in non-prompt leptons, and  
 1002 it is used in the fake factor method for estimating the non-prompt background, discussed in detail  
 1003 in Section 5.3.4. Jets are only required to pass one set of selection criteria. These selections are  
 1004 detailed in the following sections and summarized in Table 5.3 for muons, Table 5.4 for electrons,  
 1005 and Table 5.5 for jets.

### 1006 5.2.1.1 Muon candidate selection

1007 Cuts on muon  $p_T$  serve to reject low momentum leptons from background processes and additional  
 1008 collisions from pileup events. Preselected muons must have  $p_T > 6$  GeV and signal muons  $p_T >$   
 1009 27 GeV. The  $p_T$  requirement for loose muons is lower than for signal muons,  $p_T > 15$  GeV, for  
 1010 reasons that are discussed in Section 5.3.4. **TODO:** reference proper subsection when it's done  
 1011 Muons are required to fall within the detector's  $\eta$  acceptance:  $|\eta| < 2.7$  for preselected muons,  
 1012 which is tightened to  $|\eta| < 2.5$  for the signal muons.

1013 Cuts on the transverse and longitudinal impact parameters are applied to ensure that the can-  
 1014 didate muon originated from the primary particle interaction and not some other source, such as a  
 1015 heavy flavor decay. The preselection and the loose selection both have looser requirements on the  
 1016 transverse impact parameter significance ( $d_0/\sigma_{d_0}$ ) than the signal selection; all three have the same  
 1017 requirement on the transverse impact parameter ( $|z_0 \times \sin \theta|$ ).

Finally, the muon candidates are required to pass a particle identification and an isolation criteria as defined in [51]. The methods used in constructing the identification and isolation workingpoints are described in more detail in Section 3.2.4.2. The muon identification serves to select prompt muons with high efficiency and well measured momenta. This analysis uses two different workingpoints, **Loose** for preselected muons and **Medium** for loose and signal muons, where **Medium** muons are a tighter subset of those that pass the **Loose** requirement. Muon isolation is a measurement of detector activity around the muon candidate, and it is measured with both track-based and calorimeter-based variables. The isolation workingpoint used for the signal muons, **Gradient**, is defined such that there is 90% or better background rejection efficiency for 25 GeV muons, and 99% efficiency at 60 GeV. There is no minimum isolation requirement for preselected or loose muons. Loose muons are additionally required to fail one or both of the signal transverse impact parameter cut and signal isolation requirement.

#### Muon preselection

Momentum cut	$p_T > 6$ GeV
Angular acceptance	$ \eta  < 2.7$
Longitudinal impact parameter	$ z_0 \times \sin \theta  < 0.5$ mm
Transverse impact parameter	$d_0/\sigma_{d_0} < 10$
Particle identification	<b>Loose</b>

#### Muon signal selection

Momentum cut	$p_T > 27$ GeV
Angular acceptance	$ \eta  < 2.5$
Longitudinal impact parameter	$ z_0 \times \sin \theta  < 0.5$ mm
Transverse impact parameter	$d_0/\sigma_{d_0} < 3$
Particle identification	<b>Medium</b>
Particle isolation	<b>Gradient</b>

#### Muon loose selection

Momentum cut	$p_T > 15$ GeV
Angular acceptance	$ \eta  < 2.5$
Longitudinal impact parameter	$ z_0 \times \sin \theta  < 0.5$ mm
Transverse impact parameter	$d_0/\sigma_{d_0} < 10$
Particle identification	<b>Medium</b>
Fail signal transverse impact parameter and/or isolation cuts	

Table 5.3: Muon selection criteria. All muons are required to pass the preselection (top), and then either the signal (middle) or loose (bottom) criteria is applied to the preselected electrons.

---

1030    **5.2.1.2 Electron candidate selection**

1031    The electron candidate selections are very similar to those for muons. The  $p_T$  cut starts at  $p_T >$   
 1032    6 GeV for the preselection, increases to  $p_T > 20$  GeV for loose electrons, and finally to  $p_T > 27$  GeV  
 1033    for signal electrons. The  $|\eta|$  cut for electrons requires  $|\eta| < 2.47$  for all electrons, with the region  
 1034     $1.37 \leq |\eta| \leq 1.52$  removed from loose and signal electrons. This region is where the electromagnetic  
 1035    calorimeter transitions from the barrel to the endcaps and is not fully instrumented. Both the  
 1036    transverse and longitudinal impact parameter cuts are the same for all electron selections.

1037    The electron particle identification uses a multivariate likelihood technique (LH) [52] detailed  
 1038    in Section 3.2.4.3. Preselected electrons must pass the loosest LH workingpoint `LooseLH` with  
 1039    an additional requirement that there be a reconstructed track hit in the first layer of the pixel  
 1040    detector (a so-called *B*-layer hit). The LH requirement for the loose and signal electrons the tightness  
 1041    of the identification using `MediumLH` and `TightLH`, respectively. As for isolation, the `Gradient`  
 1042    workingpoint is required for signal electrons only. The loose electrons must fail one or both of the  
 1043    signal identification and isolation requirements.

1044    **5.2.1.3 Jet candidate selection**

1045    The final objects that need to pass selection are jets. Jets are clustered using the anti- $k_t$  algo-  
 1046    rithm [53] within a radius of  $\Delta R = 0.4$ . The jets are then calibrated using  $E_T$ - and  $\eta$ -dependent  
 1047    correction factors that are trained using MC simulations [54]. These calibrated jets are then re-  
 1048    quired to have  $p_T > 30$  GeV if they lie in the forward regions of the detector ( $2.4 < |\eta| < 4.5$ ) and  
 1049     $p_T > 25$  GeV in the central region ( $|\eta| \leq 2.4$ ). In order to suppress pileup jets, the so-called jet-  
 1050    vertex-tagger (JVT) discriminant associates a jet with the primary interaction vertex [55]; central  
 1051    jets with  $p_T > 60$  GeV are required to pass the `Medium` JVT workingpoint, which corresponds to  
 1052    an average efficiency of over 92%. Finally, the jets are required to be separated by selected prompt  
 1053    leptons by at least  $\Delta R(j, l) > 0.3$ .

1054    **5.2.1.4 Treatment of overlapping objects**

1055    In the event that one or more objects are reconstructed very close to each other, there is the  
 1056    possibility for double-counting if both originated from the same object. The procedure by which  
 1057    this ambiguity is resolved is called *overlap removal* (OR). The standard ATLAS recommendation  
 1058    for OR is implemented in this analysis [56, 57] and is summarized in Table 5.6.

Electron preselection	
Momentum cut	$p_T > 6$ GeV
Angular acceptance	$ \eta  < 2.47$
Longitudinal impact parameter	$ z_0 \times \sin \theta  < 0.5$ mm
Transverse impact parameter	$d_0/\sigma_{d_0} < 5$
Particle identification	<b>LooseLH + <math>B</math>-layer hit</b>

Electron signal selection	
Momentum cut	$p_T > 27$ GeV
Angular acceptance	$ \eta  < 2.47$ , excluding $1.37 \leq  \eta  \leq 1.52$
Longitudinal impact parameter	$ z_0 \times \sin \theta  < 0.5$ mm
Transverse impact parameter	$d_0/\sigma_{d_0} < 5$
Particle identification	<b>TightLH</b>
Particle isolation	<b>Gradient</b>

Electron loose selection	
Momentum cut	$p_T > 20$ GeV
Angular acceptance	$ \eta  < 2.47$ , excluding $1.37 \leq  \eta  \leq 1.52$
Longitudinal impact parameter	$ z_0 \times \sin \theta  < 0.5$ mm
Transverse impact parameter	$d_0/\sigma_{d_0} < 5$
Particle identification	<b>MediumLH</b>
Fail signal identification and/or isolation cuts	

Table 5.4: Electron selection criteria. All electrons are required to pass the preselection (top), and then either the signal (middle) or loose (bottom) criteria is applied to the preselected electrons.

Jet selection	
Momentum cut	$p_T > 30$ GeV for $2.4 <  \eta  < 4.5$ $p_T > 60$ GeV for $ \eta  < 2.4$
JVT cut	<b>Medium</b>
Jet-lepton separation	$\Delta R(j, l) > 0.3$

Table 5.5: Jet selection criteria. All jets are required to pass the above selection in order to be used in the analysis.

1059 Since electrons leave a shower in the EM calorimeter, every electron has a jet associated with  
 1060 it. Therefore, any jets close to an electron (within  $\Delta R(e, j) < 0.2$ ) are rejected due to the high  
 1061 probability that they are the same object. On the other hand, when jets and electrons overlap  
 1062 within a large radius of  $0.2 < \Delta R(e, j) < 0.4$ , it is likely that the electron and jet both are part of  
 1063 a heavy-flavor decay, and the electron is rejected.

1064 High energy muons can produce photons via bremsstrahlung radiation or collinear final state  
 1065 radiation which results in a nearby energy deposit in the calorimeters. Non-prompt muons from  
 1066 hadronic decays produce a similar signature; however, in this case the jet has a higher track multiplicity  
 1067 in the ID. It is possible to address both cases by rejecting the jet when the ID track multiplicity  
 1068 is less than three and otherwise rejecting the muon for jets and muons within  $\Delta R(\mu, j) < 0.4$ .

1069 In addition to the case above where muon bremsstrahlung results in a nearby reconstructed jet,  
 1070 the ID track from the muon and the calorimeter energy deposit can lead to it being reconstructed  
 1071 as an electron. In this case, if both a muon and an electron share a track in the ID, the muon is  
 1072 kept and the electron is rejected, unless the muon is calorimeter-tagged<sup>11</sup>, in which case the muon  
 1073 is removed in favor of the electron.

Overlap	Check	Result (remove → keep)
Electron & Jet	$\Delta R(e, j) < 0.2$	Jet → electron
	$0.2 < \Delta R(e, j) < 0.4$	Electron → jet
Muon & Jet	$\Delta R(\mu, j) < 0.4$ and Jet $N_{ID}$ tracks $< 3$	Jet → muon
	$\Delta R(\mu, j) < 0.4$ and Jet $N_{ID}$ tracks $\geq 3$	Muon → jet
Electron & Muon	Shared ID track	Electron → muon
	Shared ID track & muon is calo-tagged	Muon → electron

Table 5.6: Summary of the overlap removal procedure used in the analysis. If the criteria in the “check” column is met, in the “result” column, the object on the left of the arrow is removed in favor of the object on the right.

### 1074 5.2.2 Signal event selection

1075 After the objects have been selected, cuts are applied on a per-event level to select  $W^\pm W^\pm jj$  signal  
 1076 events. The event selection is summarized in Table 5.8 and is detailed in this section. It includes  
 1077 the results of an optimization performed using a multidimensional grid scan.

1078 The initial event selection begins by choosing events that pass one or more of the trigger re-  
 1079 quirements listed in Table 5.7. At least one signal lepton is “matched” to a passed trigger in order

<sup>11</sup>A calorimeter-tagged (CT) muon is a muon that is identified by matching an ID track to a calorimeter energy deposit. CT muons have relatively low reconstruction efficiency compared to those measured by the MS, but can be used to recover acceptance in regions of the detector where the MS does not have full coverage [51].

1080 to ensure that it was indeed a signal lepton that fired the trigger. A collection of *event cleaning*  
 1081 cuts must also be passed in order to remove events collected during periods in which one or more  
 1082 components of the detector was not operating optimally. Finally, the events are required to contain  
 1083 at least one interaction vertex. An event can have multiple reconstructed vertices from additional  
 1084 proton-proton collisions that occurred in the same bunch crossing. In this case, the *primary vertex*  
 1085 is determined by choosing the vertex with the largest sum of the  $p_T^2$  of its associated tracks.

	2015 data	2016 data
Electrons	$p_T > 24$ GeV and Medium ID	$p_T > 26$ GeV and Tight ID and Loose isolation
	$p_T > 60$ GeV and Medium ID	$p_T > 60$ GeV and Medium ID
	$p_T > 120$ GeV and Loose ID	$p_T > 140$ GeV and Loose ID
Muons	$p_T > 20$ GeV and Loose isolation $p_T > 50$ GeV	$p_T > 26$ GeV and Medium isolation $p_T > 50$ GeV

Table 5.7: Summary of trigger requirements for electrons and muons for  $\sqrt{s} = 13$  TeV data collected in 2015 and 2016. At least one of the triggers must be satisfied.

1086 Events are then required to contain exactly two signal leptons with the same electric charge.  
 1087 The dilepton pair must have a combined invariant mass of  $m_{ll} \geq 20$  GeV in order to suppress low  
 1088 mass Drell-Yan backgrounds. Two additional selections are applied to events in the  $ee$ -channel:  
 1089 both electrons are required to have  $|\eta| < 1.37$  with an invariant mass at least 15 GeV away from  
 1090 the  $Z$ -boson mass to reduce events where one electron is reconstructed with the wrong charge (this  
 1091 background will be discussed in more detail in Section 5.3 TODO: Replace with proper subsection  
 1092 once it's written). To suppress backgrounds from events with more than two leptons, events with  
 1093 more than two leptons passing the preselection are vetoed.

1094 Missing transverse energy ( $E_T^{\text{miss}}$ ) represents any particles that escape the detector without  
 1095 being measured, such as neutrinos, and is defined as the magnitude of the vector sum of transverse  
 1096 momenta of all reconstructed objects. It can be difficult to calculate accurately, as it involves  
 1097 measurements from all subsystems within the detector, and it is sensitive to any corrections that  
 1098 may be applied to the reconstructed physics objects [58]. These corrections, including the momentum  
 1099 smearing for muons, energy scale and smearing for electrons, and jet calibrations, are propagated  
 1100 to the  $E_T^{\text{miss}}$  calculation. Events are required to contain  $E_T^{\text{miss}} > 30$  GeV in order to account for the  
 1101 two neutrinos from the  $W$  boson decays.

1102 At least two jets are required. The leading and subleading jets must have  $p_T > 65$  GeV and  
 1103  $p_T > 35$  GeV, respectively, and are referred to as the *tagging jets*. Events are vetoed if they contain  
 1104 one or more jets that have been tagged as a  $b$ -jet to suppress backgrounds from heavy flavor decays

(especially top quark events). The  $b$ -tagging algorithm used by ATLAS is a boosted decision tree (BDT) called MV2c10, and this analysis uses a workingpoint with 85% efficiency [59].

Finally, cuts are applied on the VBS signature outlined in Section 5.0.3. The tagging jets are required to have a dijet invariant mass  $m_{jj} > 200$  GeV and be separated in rapidity by  $|\Delta y_{jj}| > 2.0$ . This preferentially selects the VBS EWK events over the QCD-produced  $W^\pm W^\pm jj$  events.

Event selection	
Event preselection	Pass at least one trigger with a matched lepton Pass event cleaning At least one reconstructed vertex
Lepton selection	Exactly two leptons passing signal selection Both signal leptons with the same electric charge $ \eta  < 1.37$ and $ M_{ee} - M_Z  > 15$ GeV ( $ee$ -channel only) Veto events with more than two preselected leptons
Missing transverse energy	$E_T^{\text{miss}} \geq 30$ GeV
Jet selection	At least two jets Leading jet $p_T > 65$ GeV Subleading jet $p_T > 35$ GeV $m_{jj} > 200$ GeV $N_{b\text{-jet}} = 0$ $ \Delta y_{jj}  > 2.0$

Table 5.8: The signal event selection.

### 5.3 Background estimations

The major sources of background events are summarized in Section 5.0.4, and the methods used to estimate them are detailed in this section. Prompt backgrounds from  $ZZ$  and  $t\bar{t}V$  are estimated directly from MC simulations. The shape of the  $WZ$  and  $V\gamma$  backgrounds are taken from MC, and the predicted yeilds are normalized to the data predictions in dedicated control regions, as outlined in Sections 5.3.1 and 5.3.2, respectively. Opposite sign events with a charge misidentified electron are estimated by a data-driven background method which is summarized in Section 5.3.3. Finally, a *fake factor* method is used to estimate the contributions from non-prompt backgrounds and is the subject of Section 5.3.4.

#### 5.3.1 Estimation of the $WZ$ background

The dominant background involving prompt leptons comes from  $WZ + \text{jets}$  events. The contribution is estimated from MC simulation and normalized to data in a control region enriched in  $WZ$  events

defined by the same event selection as Table 5.8 for the signal region, with the following changes applied to increase the purity of the  $WZ$  process:

- The third lepton veto is inverted, requiring a third lepton with  $p_T > 15$  GeV
- Two of the leptons must make a same-flavor opposite-sign pair. If more than one pair exists, the one with  $m_{ll}$  closest to the  $Z$  boson mass is chosen.
- The trilepton invariant mass is required to be  $m_{lll} > 106$  GeV to reduce contributions from  $Z\gamma$  and  $Z+jets$

Once the event yields in the control region are calculated, they are propagated to the final signal region fit, detailed in Section 5.4.1, in a single bin combining all the lepton channels. The systematic uncertainties of the  $WZ$  background are also calculated at this time. The event yields for the  $WZ$  control region are listed in Table 5.9, and distributions of the leading lepton  $p_T$  and  $\eta$  as well as trilepton invariant mass  $m_{lll}$  are found in Figures 5.10 and 5.9, respectively.

Event yields in the $WZ$ control region	
$WZ$	$197.9 \pm 1.4$
$ZZ$	$14.1 \pm 0.3$
Triboson	$1.26 \pm 0.1$
top	$10.8 \pm 1.1$
$Z\gamma$	$3.1 \pm 1.1$
$Z+jets$	$2.5 \pm 1.4$
Total prediction	$229.7 \pm 2.5$
Data	$201 \pm 14.2$

Table 5.9: Event yields in the  $WZ$  control region before normalization. All lepton flavor channels are combined.

### 5.3.2 Estimation of the $V\gamma$ background

Events from  $V\gamma$  processes can pass selection if the photon converts into an  $e^+e^-$  pair and one of the electrons passes the selection criteria. The background is estimated from MC simulations which are then scaled by a normalization factor calculated from a control region enriched in  $Z(\mu^+\mu^-)\gamma$  events. This control region selects two opposite-sign muons and an additional electron that is assumed to come from the photon conversion. The full event selection is detailed in Table 5.10.

The  $Z\gamma$  MC samples available do not cover the full range of  $p_T^\gamma$  and  $\Delta R(\gamma, l)$ ; thus, additional Drell-Yan samples ( $Z+jets$ ) are used to fill out the phase space. Overlap between the two samples

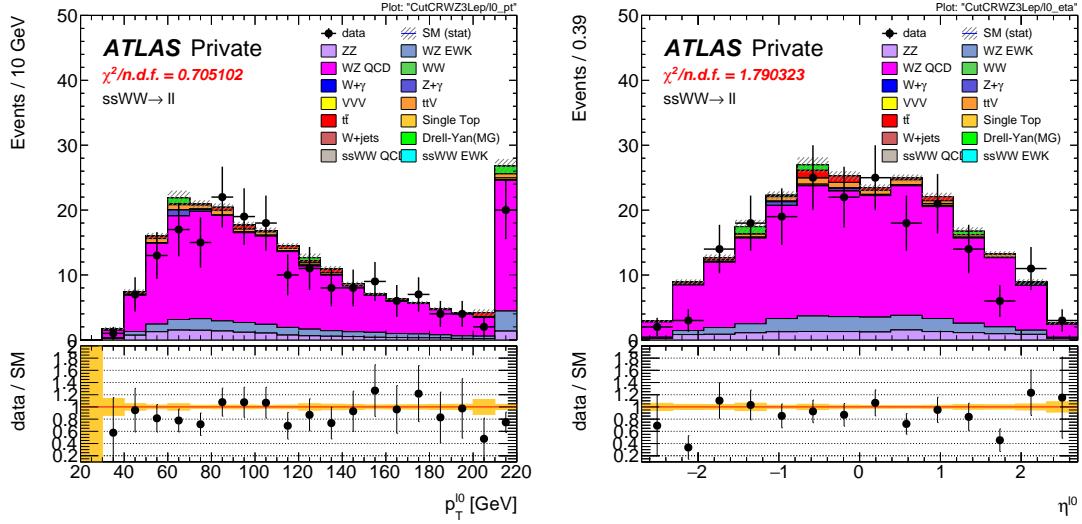

Figure 5.9: Leading lepton  $p_T$  (left) and  $\eta$  (right) distributions in the  $WZ$  control region before normalization. All lepton channels are combined.

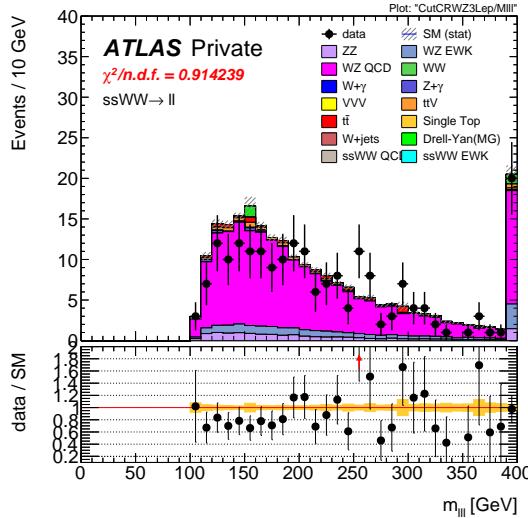

Figure 5.10: Trilepton invariant mass  $m_{lll}$  distribution in the  $WZ$  control region before normalization. All lepton channels are combined.

$V\gamma$ control region
Exactly two muons with $p_T > 27$ GeV and $p_T > 20$ GeV
Exactly one additional electron with $p_T > 15$ GeV
Remove overlap between $Z+jets$ and $Z\gamma$
Di-muon + photon invariant mass $75 < M_{\mu\mu\gamma} < 100$ GeV
$E_T^{\text{miss}} < 30$ GeV

Table 5.10: Selection criteria for the  $V\gamma$  control region.

are removed based to avoid double counting. Events with final state photons at truth level are checked to ensure that the photon did not originate from a hadronic decay. Cuts on  $p_T^\gamma > 10$  GeV and  $\Delta R(\gamma, l) > 0.1$  are then applied at generator level, and  $Z\gamma$  events that fail and  $Z+jets$  events that pass this additional selection are removed.

The normalization factor is calculated directly from the event yields in the  $V\gamma$  control region rather than in the signal fit, as is done for the  $WZ$  background. The event yields are listed in Table 5.11, and the normalization factor is determined to be 1.77. No MC events from  $Z\gamma$  processes survive the full event selection; thus, the scaling is only applied to the  $W\gamma$  background in the signal region. A systematic uncertainty of 44% is assigned to the background based off of the uncertainties in the calculation of the normalization factor.

Event yields in the $V\gamma$ control region	
$Z\gamma$	$24.6 \pm 3.3$
$Z+jets$	$3.0 \pm 1.5$
diboson + triboson	$6.7 \pm 0.3$
top	$1.5 \pm 0.5$
Total prediction	$35.8 \pm 3.7$
Data	$57 \pm 7.6$

Table 5.11: Event yields in the  $V\gamma$  control region. The  $V\gamma$  scale factor of 1.77 is calculated by scaling up the  $Z\gamma$  and  $Z+jets$  backgrounds to account for the difference between the data and predicted total background.

### 5.3.3 Estimation of backgrounds from charge misidentification

If an electron's charge is mis-reconstructed, it can lead to a real, opposite-sign lepton pair passing the same-sign requirement in the event selection. There are two primary reasons this can occur:

1. An electron emits a photon via bremsstrahlung which then converts into an electron-positron pair, and the conversion track with the wrong electric charge is matched to the original electron. This is the dominant process leading to charge flip, and it is highly dependent on the electron  $\eta$  due to the different amount of detector material the electron passes through.
2. The curvature of the electron's track is mismeasured, resulting in the wrong charge being assigned. This process is dependent on the momentum of the electron, as its track becomes more straight as the momentum of the electron increases.

In order to estimate this background, the rate at which an electron's charge is misidentified is calculated from  $Z \rightarrow e^+e^-$  MC simulation. It is known that the MC does not perfectly model

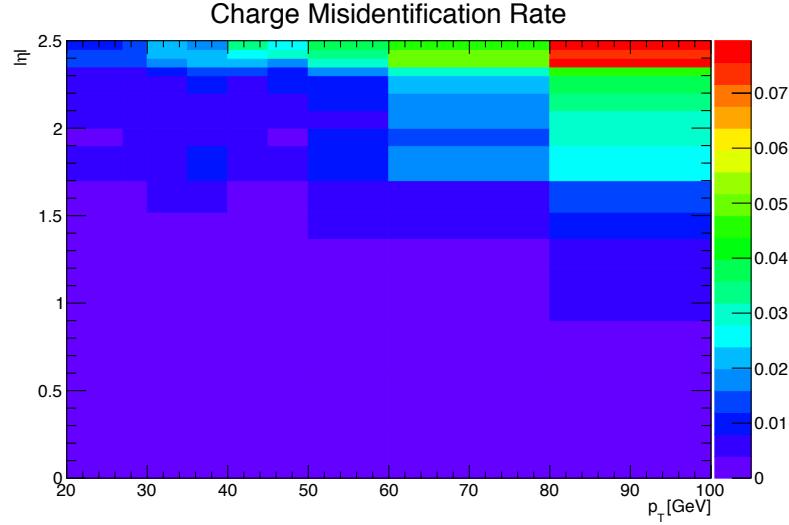

Figure 5.11: Charge misidentification rates for electrons as a function of  $|\eta|$  and  $p_{\text{T}}$ . Rates are calculated from  $Z \rightarrow e^+e^-$  MC after applying scale factors to approximate the charge mis-ID rates in data.

the material effects leading to charge flip; as a result, scale factors are applied to the MC in order for it to better reflect the real performance. These scale factors are obtained from the ratio of charge mis-ID rates in data and uncorrected MC in [26] following the method outlined in [60]. Once the scale factors are applied, the charge misidentification rate  $\varepsilon$  can be extracted by comparing the electron's reconstructed charge with the charge of its truth particle:

$$\varepsilon(\eta, p_{\text{T}}) = \frac{N_{\text{wrong charge}}}{N_{\text{prompt electrons}}} \quad (5.1)$$

The charge mis-ID rate is calculated in bins of electron  $|\eta|$  and  $p_{\text{T}}$  and varies from below 0.1% in the

central region of the detector up to 8% in the forward regions for high  $p_{\text{T}}$  (above 90 GeV) electrons.

A two-dimensional plot of  $\varepsilon$  can be found in Figure 5.11.

Given the charge flip rate  $\varepsilon(\eta, p_{\text{T}})$ , the rate at which an electron has its charge correctly reconstructed is  $(1 - \varepsilon)$ . Thus there are three possible combinations of charge identification, assuming a two-electron event:

- 1175 1. Both electrons are reconstructed correctly:  $(1 - \varepsilon)^2$
- 1176 2. Both electrons are mis-reconstructed:  $\varepsilon^2$
- 1177 3. Only one electron is mis-reconstructed:  $2\varepsilon(1 - \varepsilon)$

1178 In order to estimate the size of the background from charge misidentification, opposite-sign events  
 1179 are selected using the default event selection for a given signal or control region with the same-sign  
 1180 requirement inverted. These events are then weighted by the probability for one of the electrons to  
 1181 be reconstructed with the wrong charge:

$$\omega = \frac{\varepsilon_1(1 - \varepsilon_2) + \varepsilon_2(1 - \varepsilon_1)}{(1 - \varepsilon_1)(1 - \varepsilon_2) + \varepsilon_1\varepsilon_2} \quad (5.2)$$

1182 where the subscripts 1 and 2 refer to the leading and subleading electrons, respectively, and  $\varepsilon_i$  is a  
 1183 function of the  $\eta$  and  $p_T$  of the  $i^{\text{th}}$  electron. In the case of an event with only one electron and one  
 1184 muon, Equation 5.2 simplifies:

$$\omega = \frac{\varepsilon}{1 - \varepsilon} \quad (5.3)$$

1185 This method assumes that there is little contamination from fake electrons in the opposite-sign  
 1186 sample, and this has been verified with MC simulation.

1187 Additionally, charge-flipped electrons tend to be reconstructed with lower energy when compared  
 1188 to electrons with the correct charge. This is due to energy loss from the material interactions that  
 1189 can cause the charge to be misidentified. A correction factor is calculated from MC simulations,  
 1190 comparing the  $p_T$  of the truth electron to its reconstructed counterpart:

$$\alpha = \frac{\left(\frac{p_T^{\text{reco}}}{p_T^{\text{truth}}} - 1\right)_{\text{correct charge}}}{\left(\frac{p_T^{\text{reco}}}{p_T^{\text{truth}}} - 1\right)_{\text{wrong charge}}} \quad (5.4)$$

1191 The correction is then applied to the  $p_T$  of the charge-flipped electron via

$$p_T = p_T^0 / (1 + \alpha) + dE \quad (5.5)$$

1192 where  $p_T^0$  is the uncorrected  $p_T$  of the electron and  $dE$  is a gaussian smearing factor centered at  
 1193 zero with a width related to the energy resolution. Since which electron is misreconstructed is never  
 1194 determined in this method, in the case of a two-electron event, the energy correction is applied  
 1195 randomly to one of the two electrons based on the probabilities for them to be charge-flipped. This  
 1196 also determines the overall sign of the event; the charge of the electron that does not receive the  
 1197 correction is taken to be the charge for both.

1198 Systematic uncertainties on the charge mis-ID rates are calculated by generating two additional  
 1199 sets of rates with the uncertainties on the scale factors varied up and down. The size of the esti-  
 1200 mated charge flip background without the energy correction applied is also taken as a systematic  
 1201 uncertainty. These systematic uncertainties are estimated to be approximately  $\pm 15\%$ .

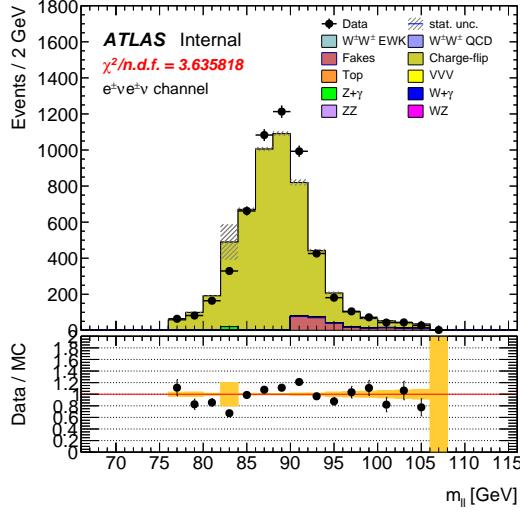

Figure 5.12: Dilepton invariant mass distribution  $m_{ll}$  for the  $ee$  channel in the same-sign inclusive VR.

### 1202 5.3.3.1 Validation of the charge misidentification estimate

1203 The performance of the charge misidentification estimation is tested in the same-sign inclusive  
 1204 validation region (VR), defined in Table 5.12. For  $ee$  events, the mass of the dilepton pair is required  
 1205 to lie within 15 GeV of the  $Z$  boson mass to increase the purity of the charge flip background.  
 1206  $t\bar{t}$  production, which can contribute to both the charge mis-ID and fake lepton backgrounds, is  
 1207 suppressed by the  $b$ -jet veto. The di-electron invariant mass is shown in Figure 5.12, and distributions  
 1208 of the leading and subleading electron  $p_T$  in the  $ee$ -channel are shown in Figure 5.13 with the  $Z$   
 1209 mass cut inverted. Agreement between data and prediction is seen within the total statistical and  
 1210 systematic uncertainties in the VR.

Same-sign inclusive VR
Exactly 2 same-sign signal leptons
$p_T > 27$ GeV for both leptons
$m_{ll} > 20$ GeV
$ m_{ee} - m_Z  > 15$ GeV ( $e^\pm e^\pm$ -channel only)
$N_{b\text{-jet}} = 0$

Table 5.12: Selection criteria for the same-sign inclusive validation region.

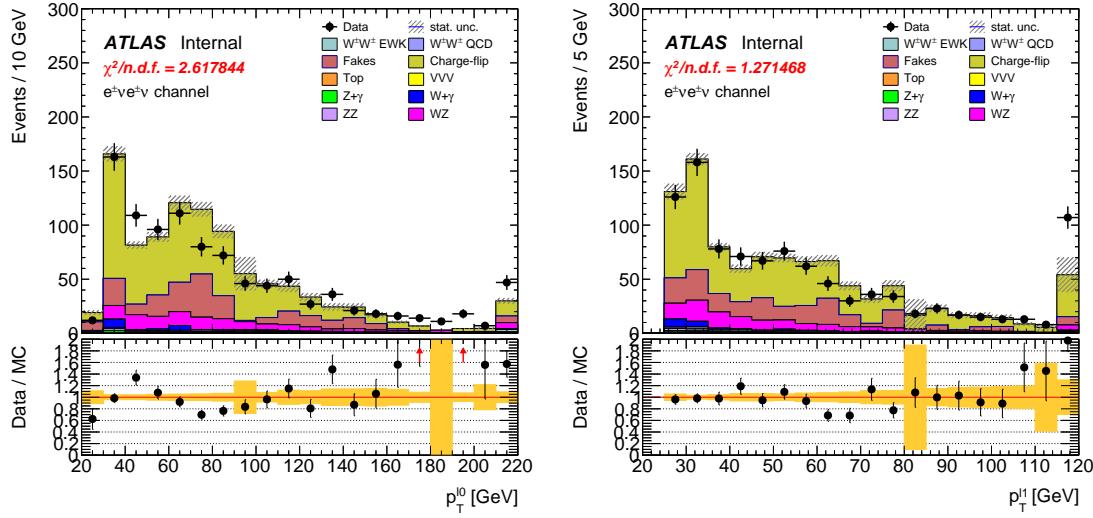

Figure 5.13:  $p_T$  distributions for the leading (left) and subleading (right) electron for the  $ee$  channel in the same-sign inclusive VR. In these plots, the cut requiring  $m_{ee}$  to fall within the  $Z$  mass window has been inverted in order to test the modelling away from the  $Z$  peak.

### 1211 5.3.4 Estimation of non-prompt backgrounds with the fake factor method

1212 Events with one prompt lepton produced in association with hadronic jets can pass the event selection  
 1213 if a jet is misidentified as a charged lepton or if a non-prompt lepton from the decay of a heavy  
 1214 flavor particle (such as  $b$ - and  $c$ -hadrons) passes the signal lepton criteria. These misidentified jets  
 1215 and non-prompt leptons are collectively referred to as *fake leptons*, or simply *fakes*. The rate at  
 1216 which a fake lepton is misidentified is generally not modelled well enough by the MC to accurately  
 1217 estimate their contributions directly from simulation. Therefore, a data-driven technique called the  
 1218 *fake factor* is used to estimate the size and shape of background processes from fake leptons. In this  
 1219 analysis, a new modification to the fake factor is used involving the particle isolation variables; the  
 1220 method is outlined in the context of the *default* fake factor in Section 5.3.4.1, and the modified fake  
 1221 factor is outlined in Section 5.3.4.2.

#### 1222 5.3.4.1 Overview of the default fake factor method

1223 The goal of the fake factor method is to measure the fake rate from real collision events in a region  
 1224 enriched in fake leptons and use it to estimate the size of the fake lepton background in a chosen  
 1225 signal or control region. This is done by creating two samples using different lepton definitions:

- 1226 1. The *nominal* sample is made up of leptons passing the signal selection.

1227     2. The *loose* sample is made up of leptons that fail the signal selection while still passing a  
 1228        loosened set of criteria. This sample is enriched in fake leptons and is orthogonal to the set of  
 1229        signal leptons.

1230   Using the sets of nominal and loose leptons, a fake factor  $f$  can be calculated in a region enriched  
 1231   in processes that are prone to producing fake leptons:

$$f = \frac{N_{\text{nominal}}}{N_{\text{loose}}} \quad (5.6)$$

1232   Since the fake rate is not expected to be constant over the entire phase space, the fake factor can  
 1233   be divided into bins:

$$f(b) = \frac{N_{\text{nominal}}(b)}{N_{\text{loose}}(b)} \quad (5.7)$$

1234   where  $b$  represents the bin number. In this analysis, the fake factor is binned in lepton  $p_T$ .

1235   In order to estimate the fake background contribution in a given signal or control region, the  
 1236   fake factor is applied to a second control region with a selection identical to the region of interest  
 1237   with one of the leptons required to satisfy the loose criteria. The region for which the background  
 1238   is estimated contains two nominal leptons and is referred to as *nominal+nominal* ( $NN$ ), and the  
 1239   associated control region where the fake factor is applied contains one nominal and one loose lepton  
 1240   and is referred to as *nominal+loose* ( $NL$ ). The fake background in a  $NN$  region can then be  
 1241   calculated as:

$$N_{NN}^{\text{fake bkg.}} = \sum_b f(b) N_{NL}(b) \quad (5.8)$$

1242   Backgrounds containing two prompt leptons can also enter the  $NL$  region if one of the leptons  
 1243   passes the nominal selection and the other passes the loose selection. Since the fake factor method  
 1244   estimates the fake background by scaling the amount of non-prompt events in the  $NL$  region, if these  
 1245   prompt contributions are not removed, they will be included in the scaling and the background  
 1246   will be overpredicted. The final estimate of the fake background becomes:

$$N_{NN}^{\text{fake bkg.}} = \sum_b f(b) (N_{NL}(b) - N_{NL}^{\text{prompt}}(b)) \quad (5.9)$$

#### 1247   **5.3.4.2 The fake factor with $p_T^{\text{cone}}$**

1248   When a jet produces a non-prompt lepton, that lepton only carries a fraction of the underlying jet's  
 1249   total momentum. Due to the isolation cut applied to the nominal leptons, they typically carry a

1250 much larger percentage of the underlying jet momentum<sup>12</sup> than the loose leptons (which are allowed  
 1251 to fail this criteria).

1252 This discrepancy in the underlying jet momentum fraction can cause problems in the calculation  
 1253 of the fake factor  $f$ . Consider the case where two separate events have jets of identical momentum,  
 1254 but one produces a non-prompt lepton that passes the nominal selection, and the other produces a  
 1255 non-prompt lepton that passes the loose selection. The loose lepton on average will have lower  $p_T$   
 1256 than the nominal lepton despite both originating from jets with the same momentum. This can be  
 1257 seen explicitly when comparing the  $p_T$  of a muon to its associated truth jet:

$$\Delta p_T(\mu, j) = \frac{p_T(j) - p_T(\mu)}{p_T(j) + p_T(\mu)} \quad (5.10)$$

1258 Since muons are not included in the jet reconstruction algorithm,  $\Delta p_T$  approximates the momentum  
 1259 of the muon compared to the rest of the jet. For muons that carry more than 50% of the jet's  
 1260 momentum,  $\Delta p_T$  will be negative and vice-versa. The  $\Delta p_T$  distributions for nominal and loose  
 1261 muons in  $t\bar{t}$  MC events is shown Figure 5.14, where a 50 GeV jet on average corresponds to a  
 1262 35 GeV nominal muon and a 20 GeV loose muon<sup>13</sup>.

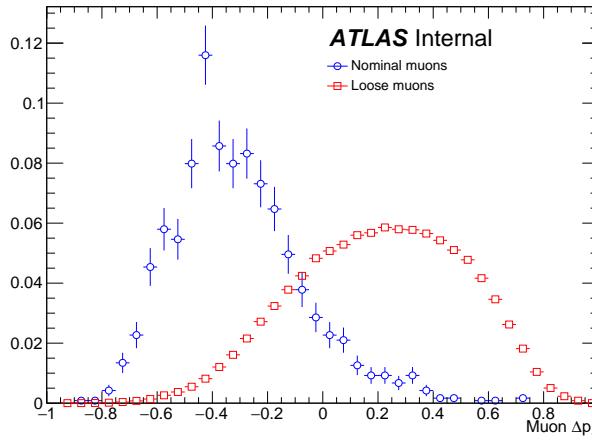

Figure 5.14:  $\Delta p_T$  distributions for nominal (blue) and loose (red) muons in simulated  $t\bar{t}$  events. Each muon has been matched to a truth-level jet. Both distributions are normalized to unit area.

1263 Since the default fake factor defined in Equation 5.7 is binned in lepton  $p_T$ , within a given bin,

<sup>12</sup>Since the isolation variables are a measure of detector activity around the lepton, if other nearby particles carried a significant portion of the jet's momentum, the lepton would likely fail this cut.

<sup>13</sup>To better illustrate the point, here the muon is added back into the jet  $p_T$ , and the corresponding muon  $p_T$  is obtained via  $\Delta p_T(\mu, j) = \frac{(p_T(j) - p_T\mu) - p_T(\mu)}{(p_T(j) - p_T\mu) + p_T(\mu)} = \frac{p_T(j) - 2p_T(\mu)}{p_T(j)}$ .

the underlying jet  $p_T$  spectrum can differ substantially between the numerator and the denominator. Additionally, these differences can vary depending on the process producing the non-prompt leptons or on the specific kinematic selections of the signal or control regions where the fake factor is applied.

Fortunately, the majority of the jet momentum not carried by the non-prompt lepton (excluding neutrinos) can be recovered using isolation variables. A track-based isolation is chosen, referred to as  $p_T^{\text{cone}}$ , and it contains the sum of the  $p_T$  of all particle tracks originating from the primary vertex within a cone of  $\Delta R < 0.3$  around the lepton. Thus, the sample of loose leptons in the denominator of the fake factor calculation is binned in  $p_T + p_T^{\text{cone}}$  rather than simply lepton  $p_T$ . Adding the isolation cone greatly reduces the difference in the fraction of the underlying jet momentum carried by the nominal and loose leptons. To check this, a new  $\Delta p_T$  is calculated between a lepton and its matched truth jet, where the truth jet  $p_T$  has been corrected to include all muons within a cone of  $\Delta R < 0.4$ :

$$p_T(j) = p_T(j_{\text{truth}}) + \sum_{\Delta R < 0.4} p_T(\mu_{\text{truth}}) \quad (5.11)$$

The  $\Delta p_T$  distributions comparing  $p_T$  and  $p_T + p_T^{\text{cone}}$  for nominal and loose leptons using the corrected jet  $p_T$  are found in Figure 5.15, and better agreement is seen between the numerator (nominal) and denominator (loose with  $p_T + p_T^{\text{cone}}$ ) distributions.

The numerator remains binned in lepton  $p_T$ , due to the fact that it is meant to mirror the signal region as closely as possible, and the signal lepton selection does not use  $p_T + p_T^{\text{cone}}$ . The impact of this is expected to be negligible due to the  $p_T^{\text{cone}}$  isolation being small for signal leptons, as shown for muons in Figure 5.16. Finally, the fake factor  $f$  becomes:

$$f(b) = \frac{N_{\text{nominal}}(b(p_T))}{N_{\text{loose}}(b(p_T + p_T^{\text{cone}}))} \quad (5.12)$$

#### 5.3.4.3 Application of the fake factor

The fake factor itself is measured from a sample data events passing a dijet selection requiring exactly one lepton (either passing the nominal or loose selections) and at least one jet. The leading jet must also be  $b$ -tagged and approximately back-to-back with the lepton in order to enhance non-prompt lepton contributions while reducing contributions from processes involving  $W$  and  $Z$  bosons.  $W$  boson events are further suppressed by requiring the sum of the  $E_T^{\text{miss}}$  and the transverse mass of the lepton and  $E_T^{\text{miss}}$  to be less than 50 GeV. The full event selection for the dijet region is summarized in Table 5.13.

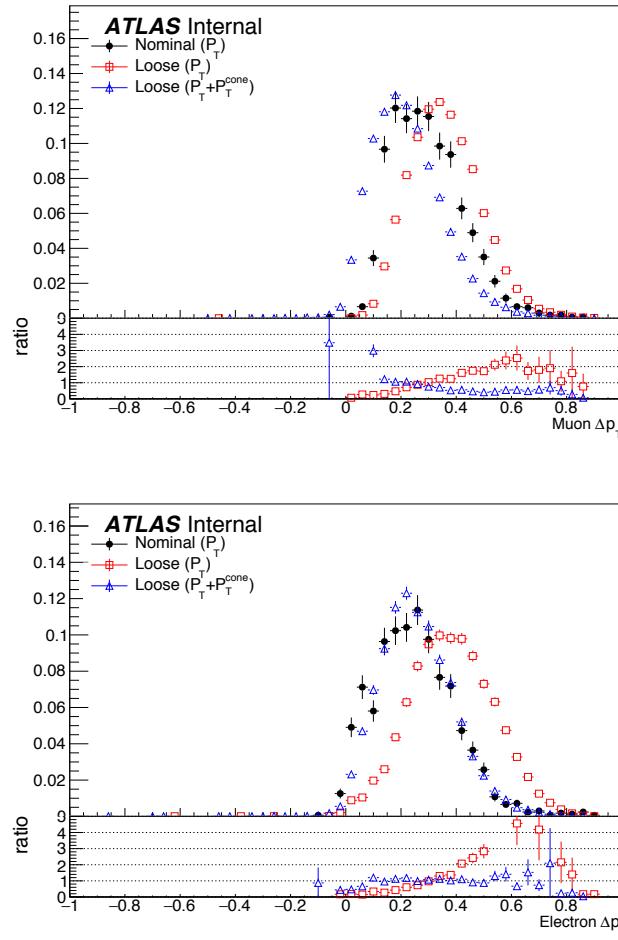

Figure 5.15:  $\Delta p_T$  distributions for muons (top) and electrons (bottom) in simulated  $t\bar{t}$  events. Each lepton has been matched to a truth-level jet, and that truth jet has had its  $p_T$  corrected to include all truth muons within a cone of  $\Delta R < 0.4$ . The nominal leptons are in black.  $\Delta p_T$  is calculated for the loose leptons using  $p_T$  (red) and  $p_T + p_T^{\text{cone}}$  (blue).

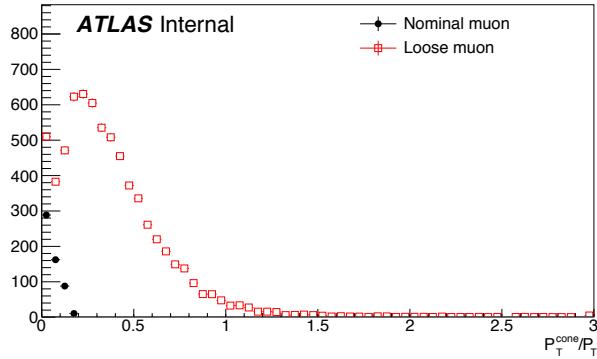

Figure 5.16: Distributions of  $p_T^{\text{cone}}/p_T$  for nominal (black) and loose (red) muons in simulated  $t\bar{t}$  events.

Dijet event selection	
Event preselection	
Exactly one lepton with $p_T > 15$ GeV	
$N_{\text{jet}} > 0$	
Leading jet is $b$ -tagged	
$p_T^{\text{lead. jet}} > 25$ GeV	
$p_T^{\text{lead. jet}} > 30$ GeV if $ \eta_j  > 2.5$	
$ \Delta\phi(l, \text{lead. jet})  > 2.8$	
$m_T(l, E_T^{\text{miss}}) + E_T^{\text{miss}} < 50$ GeV	

Table 5.13: Event selection for the dijet region used for calculating the fake factor. The selected lepton can pass either the nominal (signal) or loose selections. In the case of the nominal leptons, the  $p_T > 27$  GeV requirement is replaced with  $p_T > 15$  GeV.

1291     The numerator sample is constructed from dijet events in which the lepton passes the nominal  
 1292     (signal) selection and is binned in the lepton  $p_T$ . Similarly, the denominator sample is made up of  
 1293     the remaining dijet events where the lepton passes the loose selection and is binned in the lepton  
 1294      $p_T + p_T^{\text{cone}}$ . The nominal and loose leptons pass the signal selection<sup>14</sup> and loose selection, respectively,  
 1295     defined earlier in Table 5.3 for muons and Table 5.4 for electrons. Backgrounds from  $W$ +jets,  $Z$ +jets,  
 1296      $t\bar{t}$ , and single top processes are estimated from MC simulations requiring one lepton to be prompt  
 1297     using the truth information; these contributions are subtracted from the dijet data. The fake factor  
 1298     is then calculated using Equation 5.12 for muons and for central and forward electrons separately.  
 1299     The muon fake factor is shown in Figure 5.17, and the two electron fake factors are shown in  
 1300     Figure 5.18. The numerical values of the fake factors, including their systematic uncertainties which

<sup>14</sup>The  $p_T > 27$  GeV cut in the signal lepton selection is dropped in favor of the  $p_T > 15$  GeV requirement in the dijet selection.

1301 will be discussed in Section 5.3.4.4, are listed in Table 5.14.

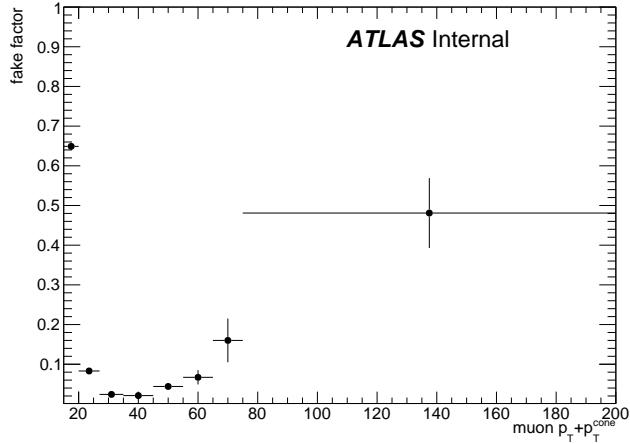

Figure 5.17: The measured fake factor as a function of muon  $p_T + p_T^{\text{cone}}$ . The error bars represent the statistical uncertainty only.

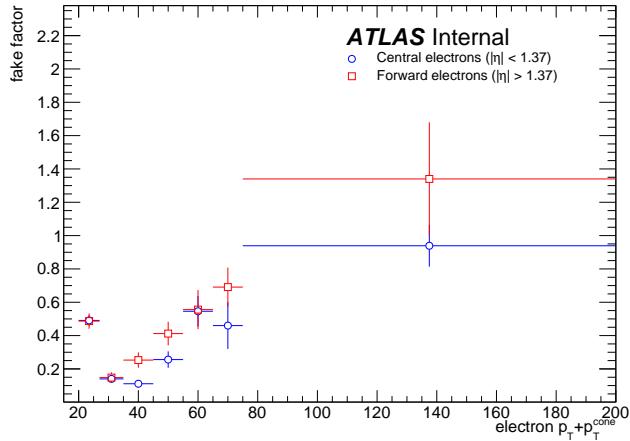

Figure 5.18: The measured fake factor as a function of electron  $p_T + p_T^{\text{cone}}$  in the central ( $|\eta| < 1.37$ , blue) and forward ( $|\eta| > 1.37$ , red) regions of the detector. The error bars represent the statistical uncertainty only.

1302 In order to properly account for the denominator being binned in  $p_T + p_T^{\text{cone}}$ , special care needs  
1303 to be taken when estimating the fake background from the  $NL$  regions. For the purposes of the  
1304 fake factor calculation, it is perhaps more intuitive to consider a loose *object* with  $p_T = p_T + p_T^{\text{cone}}$   
1305 instead of simply a loose *lepton*, as the lepton and the underlying jet are treated as a whole with this

method. When the lepton  $p_T$  cuts required by a particular signal or control region are applied to nominal and loose leptons, the cut is applied to the  $p_T$  of the nominal lepton and to the  $p_T + p_T^{\text{cone}}$  of the loose object. Similarly, when looking up the fake factor weight for a given  $NL$  event, the value taken from the bin corresponding to the  $p_T + p_T^{\text{cone}}$  of the loose object. Finally, when applying the weight to the event,  $p_T + p_T^{\text{cone}}$  is assigned as the  $p_T$  of the loose object. Figure 5.19 contains a graphical representation of this procedure.

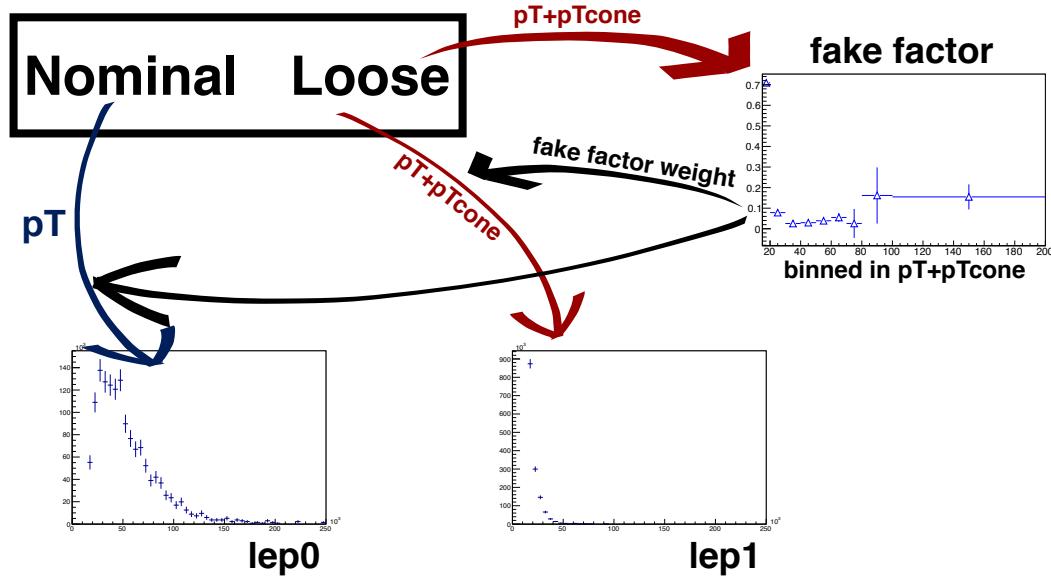

Figure 5.19: Graphical representation of the fake factor application using  $p_T + p_T^{\text{cone}}$ . The value of  $p_T + p_T^{\text{cone}}$  for the loose lepton is used to “look up” the fake factor weight which is then applied to the event. The loose lepton’s  $p_T$  becomes  $p_T + p_T^{\text{cone}}$  for the purpose of the fake background estimation.

Finally, it should be noted that the addition of  $p_T^{\text{cone}}$  to the loose object may cause the loose leptons in the denominator sample to migrate into higher bins. This results in an overall decrease in the number of loose objects in the lower  $p_T + p_T^{\text{cone}}$  bins due to there not being additional leptons at lower  $p_T$  to replace them. Since the fake factor is a ratio of the number of events in a bin, this effect causes the first few bins of the fake factor to increase, as can be seen clearly in Figure 5.17. However, the signal and control regions (and their corresponding  $NL$  regions) contain a  $p_T > 27$  GeV cut that prevents these migrations from negatively impacting the fake estimation.

1319 **5.3.4.4 Systematic uncertainties**

1320 Four sources of systematic uncertainty are considered: the dijet event selection, the prompt back-  
 1321 ground subtraction, the jet flavor composition, and residual dependence on the underlying jet  $p_T$   
 1322 spectrum. In order to measure the impact of these systematics, new fake factors are computed  
 1323 with each of the systematic variations and the differences from the nominal values are taken as the  
 1324 uncertainty.

- 1325 1. In order to estimate uncertainties due to the dijet selection, the cut on  $M_T + MET$  is varied  
 1326 by  $\pm 5$  GeV,  $\Delta\phi(l, j)$  by  $\pm 0.1$ , and the jet  $p_T$  cut by  $+5$  GeV.
- 1327 2. To estimate the systematic uncertainty on the prompt background subtraction, the MC pre-  
 1328 diction in a  $W+jets$  control region is compared to data. The discrepancy between data and  
 1329 MC is found to be approximately 10% [26]. Therefore, the prompt background used for the  
 1330 subtraction is scaled up and down by  $\pm 10\%$ .
- 1331 3. The difference in the jet flavor composition between the dijet events and the events in the  
 1332  $NL$  regions can affect the accuracy of the fake background estimation. The dijet sample is  
 1333 dominated by light jets, while the  $NL$  regions tend to be dominated by heavy flavor from  $t\bar{t}$ .  
 1334 To account for this, the fake factor is computed with a  $b$ -jet veto.
- 1335 4. To measure any residual dependence on the underlying jet  $p_T$  spectrum, the leading jet  $p_T$   
 1336 distribution is reweighted to match the  $p_T$  spectrum of truth jets that produce fake leptons  
 1337 in MC simulations. This results in an increase in the number of nominal and loose leptons at  
 1338 high momentum [26].

1339 **5.3.4.5 Results of the fake factor**

1340 The fake background contribution in the signal region is estimated by applying the fake factors  
 1341 to the equivalent  $NL$  region using Equation 5.9, where the fake factor used corresponds to the  
 1342 flavor of the loose lepton in the event. As usual, the prompt background is subtracted from the  
 1343  $NL$  events using MC simulation. Charge misidentification is handled using the same method as  
 1344 in Section 5.3.3, with an additional set of charge flip rates calculated for loose leptons. The fake  
 1345 background yields in the signal region are listed in Table 5.15. An overall uncertainty of 50% is  
 1346 assigned to the fake background estimation in  $\mu^\pm\mu^\pm$  events, and between 40% to 90% for  $e^\pm e^\pm$  and  
 1347  $\mu^\pm e^\pm$  events, including both statistical and systematic effects.

Table 5.15: Estimated yields for the fake lepton background. The estimated yield is shown in the first column together with the statistical uncertainty followed by the systematic uncertainties from variations of the the fake factors within their statistical (stat.) and systematic (syst.) uncertainties. The labels  $f_e$  and  $f_\mu$  indicate the fake factors for electrons and muons, respectively.

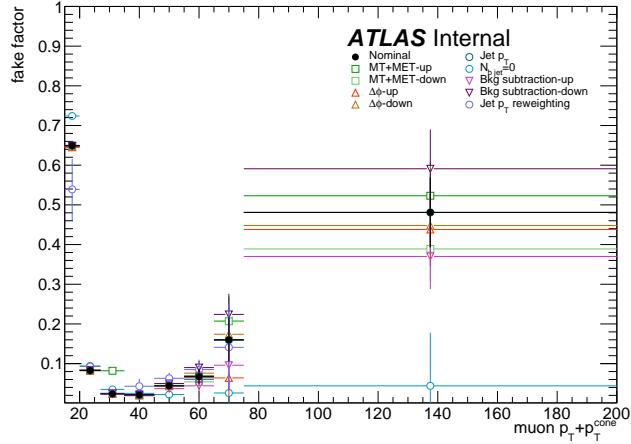

Figure 5.20: Systematic variations in the fake factor as a function of muon  $p_T + p_T^{\text{cone}}$ . The individual fake factors obtained for each systematic variation are displayed with their statistical uncertainties.

#### 1348 5.3.4.6 Validation of the fake factor

1349 The accuracy of the fake factor method is tested in several validation regions, the most sensitive  
 1350 of which is the same-sign top fakes VR (SS top VR), defined in Table 5.16. This region inverts  
 1351 the signal region's  $b$ -jet veto to accept events with exactly one  $b$ -jet. Due to this requirement, the  
 1352 dominant source of events comes from the  $t\bar{t}$  process where a  $b$ -jet fakes an isolated lepton. The  
 1353 distribution of the subleading lepton  $p_T$  in this VR is shown in Figure 5.22 for all lepton flavor  
 1354 combinations. There is good agreement between the data and the prediction, even when only taking  
 1355 into account the statistical uncertainty and not the large systematic uncertainties assigned to the  
 1356 fake estimation.

Same-sign inclusive VR
Exactly 2 same-sign signal leptons
$p_T > 27$ GeV for both leptons
$m_{ll} > 20$ GeV
$ m_{ee} - m_Z  > 15$ GeV ( $e^\pm e^\pm$ -channel only)
$N_{b\text{-jet}} = 1$
$N_{\text{jet}} \geq 2$
Leading jet $p_T > 65$ GeV
Subleading jet $p_T > 35$ GeV

Table 5.16: Selection criteria for the same-sign top fakes validation region.

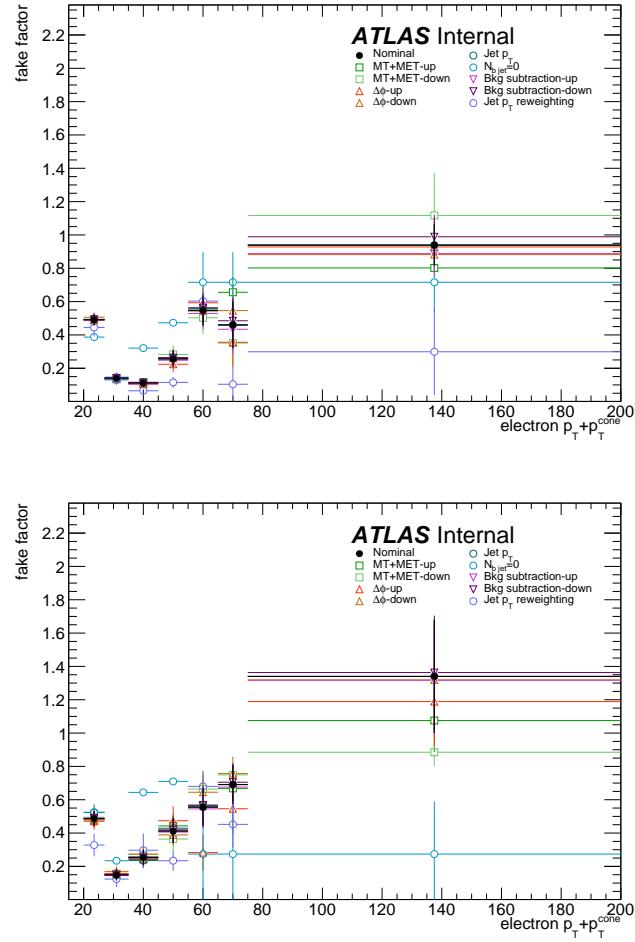

Figure 5.21: Systematic variations in the fake factor as a function of electron  $p_T + p_T^{\text{cone}}$  in the central ( $|\eta| < 1.37$ , top) and forward ( $|\eta| > 1.37$ , bottom) regions of the detector. The individual fake factors obtained for each systematic variation are displayed with their statistical uncertainties.

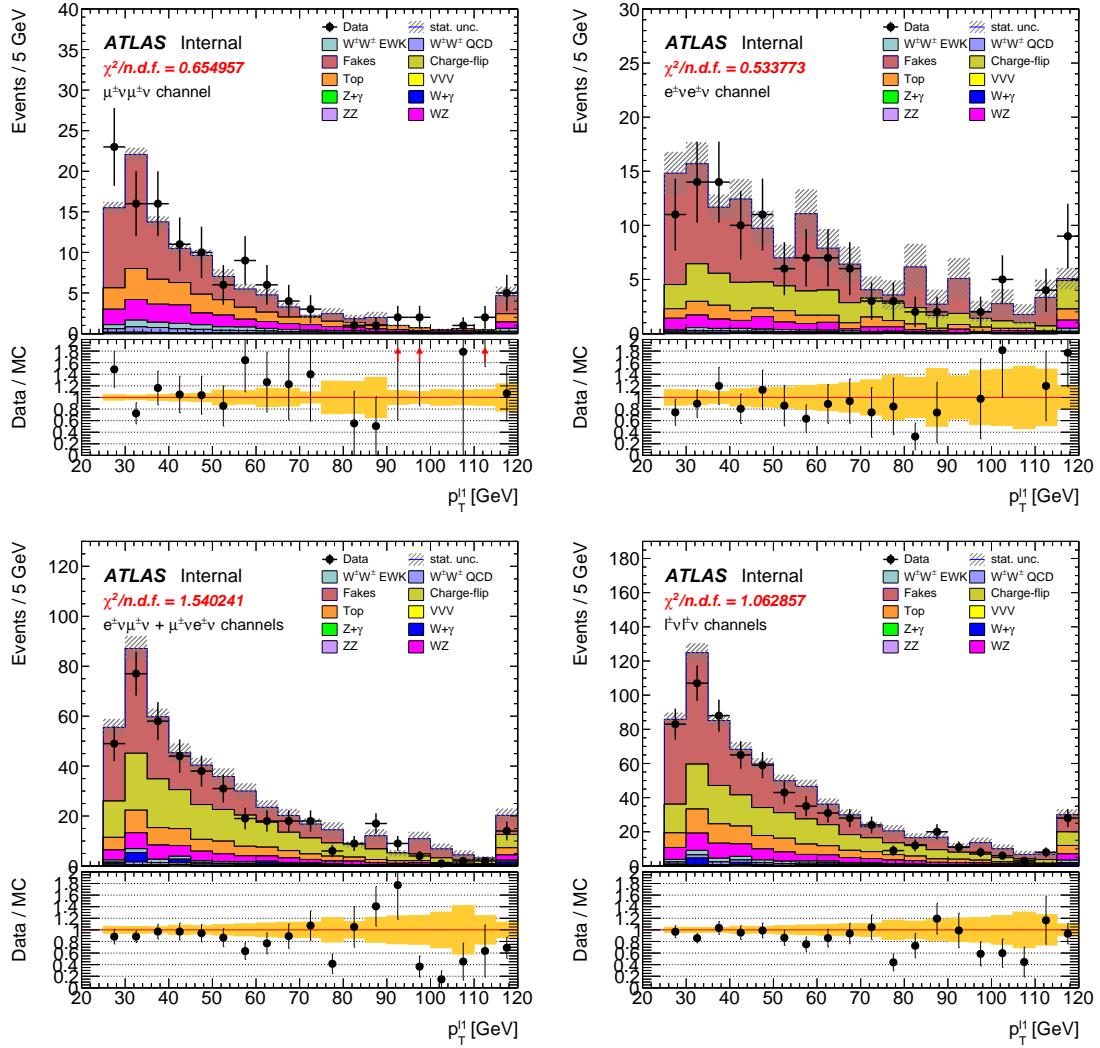

Figure 5.22: Distributions of the subleading lepton  $p_T$  in the same-sign top fakes VR for  $\mu^\pm\mu^\pm$  events (top right),  $e^\pm e^\pm$  events (top left),  $\mu^\pm e^\pm$  events (bottom left), and all events combined (bottom right). All errors are statistical only.

---

1357 **5.3.5 Reduction of  $WZ$  background using custom overlap removal**

1358 The dominant source of prompt background in this analysis comes from  $WZ$  events where both  
 1359 bosons decay leptonically. Traditionally, the background is dealt with by imposing a veto on any  
 1360 event with a third lepton passing some loose identification criteria (the so-called *trilepton veto*). In  
 1361 the case of this analysis, if one or more leptons (in addition to the two signal leptons) passed the  
 1362 preselection criteria, the event would be rejected. However,  $WZ$  events can still enter the signal  
 1363 region if one of the leptons fails the veto selection or falls outside of the detector’s acceptance.

1364 In order to understand the sources of  $WZ$  events that are not removed by the trilepton veto,  
 1365 a study was performed on truth-level leptons<sup>15</sup> on  $W^\pm W^\pm jj$  and  $WZ$  MC samples. Events with  
 1366 three truth leptons were selected, and each was matched to its reconstruction-level partner by finding  
 1367 the closest  $\Delta R(\text{truth}, \text{reco})$  and  $\Delta p_{\text{T},\text{truth},\text{reco}}$  match. For events surviving the trilepton veto, the  
 1368 two signal leptons were removed, and the remaining leptons represent real leptons that failed to  
 1369 be selected for the veto. Between 40–50% of these leptons fell outside of the eta acceptance of the  
 1370 analysis (see Figure 5.23) and were unrecoverable. The second largest source of leptons failing the  
 1371 preselection was the OR, defined in Section 5.2.1.4. The standard OR procedure appeared to be  
 1372 too aggressive in removing leptons in favor of jets, causing many three lepton events to “lose” their  
 1373 third lepton and pass the trilepton veto. Therefore a *Custom OR* was investigated which would  
 1374 replace the standard OR in the preselection and allow for better  $WZ$  rejection by removing fewer  
 1375 third leptons.

1376 **TODO:** Mention how the extra leptons in the  $W^\pm W^\pm jj$  are background leptons since there are  
 1377 only 2 from the main decay

1378 In order to construct a “custom” OR, a new quantity is defined between a lepton ( $l$ ) and a nearby  
 1379 jet ( $j$ )

$$p_{\text{T},\text{ratio}}(l, j) = \frac{p_{\text{T}l}}{p_{\text{T}j}} \quad (5.13)$$

1380 which, along with  $\Delta R(l, j)$ , will allow for more third leptons to pass the preselection. The idea  
 1381 behind including  $p_{\text{T},\text{ratio}}$  is to be able to preferentially remove background leptons originating from  
 1382 jets (i.e. those that carry a low percentage of the total jet momentum) instead of removing *any*  
 1383 lepton near to jet. The distributions of  $p_{\text{T},\text{ratio}}$  and the associated efficiency curves for muons and  
 1384 electrons can be found in Figures 5.24 and 5.26, respectively, and the distributions for  $\Delta R(\mu, j)$  for

---

<sup>15</sup>Truth particles are the particles produced directly by the MC generator before being passed through the full detector simulation, at which point they are considered *reconstruction-level* (or *reco-level*) particles.

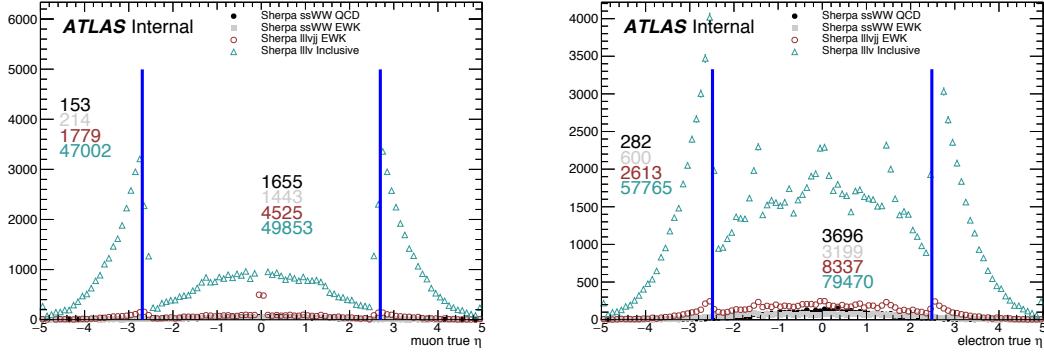

Figure 5.23: Pseudorapidity ( $\eta$ ) distributions of truth muons (top) and electrons (bottom) for Sherpa  $W^\pm W^\pm jj$  and  $WZ$  MC samples. The blue vertical lines represent the allowed  $\eta$  range for each lepton flavor. The numbers correspond to the number of raw MC events that fall within and outside of the allowed  $\eta$  range for each MC sample.

1385 muons can be found in Figure 5.25. Since all electrons have an associated jet in the calorimeters,  
 1386 the  $\Delta R(e, j)$  variable is not a good quantity to use for this custom OR.

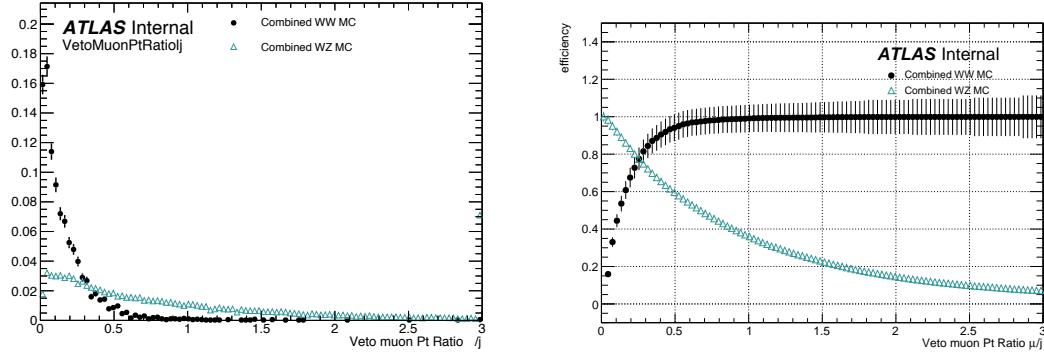

Figure 5.24: Distributions of  $p_{T,\text{ratio}}(\mu, j)$  for EWK and QCD  $W^\pm W^\pm jj$  signal (black) and  $WZ$  background (teal) for truth-matched third muons in events that pass the trilepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on  $p_{T,\text{ratio}}(\mu, j)$  at a given value on the  $x$ -axis.

1387 A workingpoint for the Custom OR was chosen by requiring 90% signal retention for muons  
 1388 and 90% background rejection for electrons. The cut on electrons was allowed to be much tighter  
 1389 because the number of signal events with a third electron is considerably smaller than for muons.  
 1390 It should be re-emphasized the signal events that are present in Figures 5.24–5.26 do not represent  
 1391 the full set of signal events, but only those with a real third lepton (which must come from some

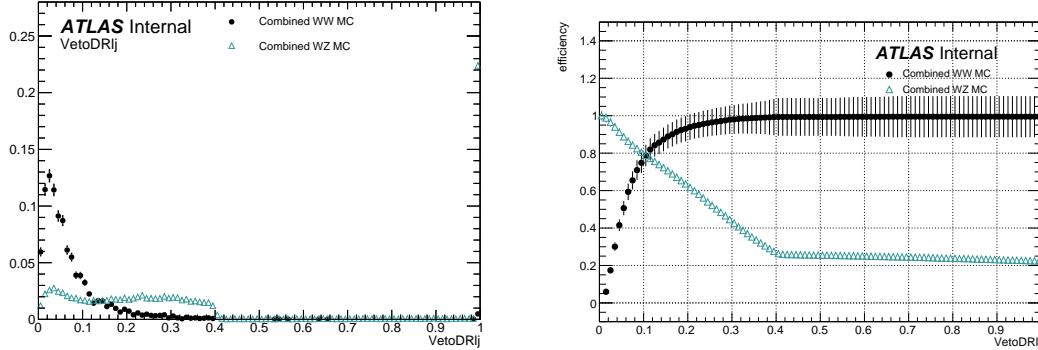

Figure 5.25: Distributions of  $\Delta R(\mu, j)$  for EWK and QCD  $W^\pm W^\pm jj$  signal (black) and  $WZ$  background (teal) for truth-matched third muons in events that pass the trilepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on  $\Delta R(\mu, j)$  at a given value on the  $x$ -axis.

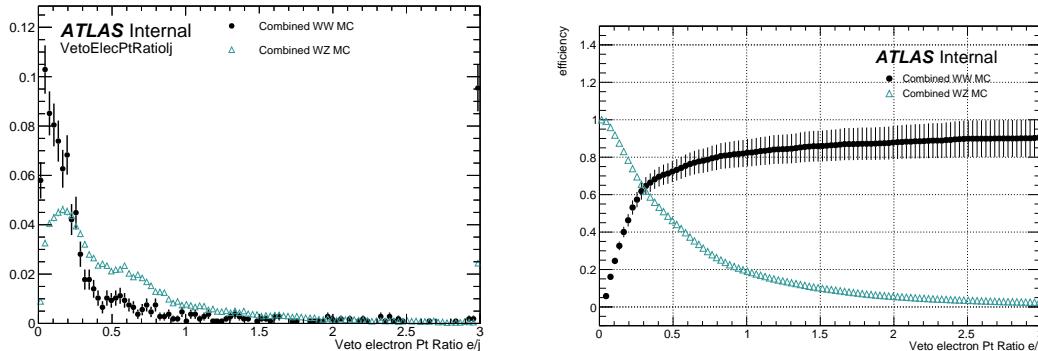

Figure 5.26: Distributions of  $p_{T,\text{ratio}}(e, j)$  for EWK and QCD  $W^\pm W^\pm jj$  signal (black) and  $WZ$  background (teal) for truth-matched third electrons in events that pass the trilepton veto. Both distributions are normalized to unit area. The associated efficiency curves are on the right where efficiency is defined as the percentage of total events that would pass a cut on  $p_{T,\text{ratio}}(e, j)$  at a given value on the  $x$ -axis.

source other than the signal  $W^\pm W^\pm jj$  process). For muons, an or of  $p_{T,\text{ratio}}(\mu, j)$  and  $\Delta R(\mu, j)$  is used to maximize the third lepton acceptance due to correlations between the quantities, as shown in Figure 5.27; for electrons, only a cut on  $p_{T,\text{ratio}}(e, j)$  is used. The Custom OR workingpoint is outlined in Table 5.17.

Custom OR Definition	
Muons	$p_{T,\text{ratio}}(\mu, j) > 0.40$ or $\Delta R(\mu, j) > 0.15$
Electrons	$p_{T,\text{ratio}}(e, j) > 0.18$

Table 5.17: Custom OR definition. Leptons must pass this selection in order to be counted for the trilepton veto.

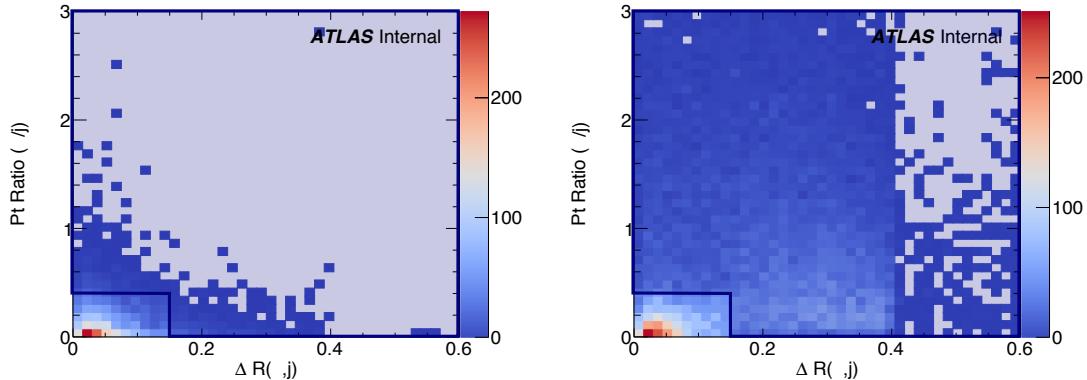

Figure 5.27: Two-dimensional plots of  $p_{T,\text{ratio}}(\mu, j)$  vs  $\Delta R(\mu, j)$  for truth-matched third muons in events that pass the trilepton veto for EWK and QCD  $W^\pm W^\pm jj$  signal (left) and  $WZ$  background (right). The blue overlay indicates the area in which the third leptons will pass the custom OR and result in the event failing the trilepton veto.

Tests of the performance of the Custom OR yield promising results, with approximately 20% reduction in  $WZ$  background compared to less than 2% signal loss in the signal region. Unfortunately, due to differences between the primary analysis framework and the one used for testing, in practice the gains in  $WZ$  rejection are not nearly as substantial, and ultimately the Custom OR is not included in the final analysis. However, it is still a potentially useful tool for improving background rejection via lepton number vetoes in analyses with overly aggressive OR procedures.

#### 5.4 Cross section measurement

The  $W^\pm W^\pm jj$  EWK cross section is extracted from the signal region using a maximum-likelihood fit applied simultaneously to four  $m_{jj}$  bins in the signal region as well as to the low- $m_{jj}$  and  $WZ$

control regions. For the fit and cross section extraction, the signal region is defined as in Table 5.8 with the dijet invariant mass requirement raised to  $m_{jj} > 500$  GeV. The low- $m_{jj}$  region is defined to mirror the signal region exactly with the dijet invariant mass inverted to  $200 < m_{jj} < 500$  GeV, and the  $WZ$  control region is defined previously in Section 5.3.1.

The signal and low- $m_{jj}$  regions are split into six channels based on the flavor and charge of the dilepton pair:  $\mu^+\mu^+$ ,  $\mu^-\mu^-$ ,  $\mu^+e^+$ ,  $\mu^-e^-$ ,  $e^+e^+$ , and  $e^-e^-$ . This split by charge increases the sensitivity of the measurement due to the  $W^+/W^-$  charge asymmetry at hadron colliders favoring the production of  $W^+$  bosons [61]. Since the signal events contain two  $W$  bosons, the signal strength compared to charge-symmetric backgrounds is much greater in the  $++$  channels for both charges combined. The  $WZ$  control region is included in the fit as a single bin ( $l^\pm l^\pm l^\pm$ ).

The maximum likelihood fit and cross section extractions are outlined in Sections 5.4.1 and 5.4.3, respectively. The results of the cross section measurement and of the analysis as a whole are presented in Section 5.6.

#### 5.4.1 Maximum likelihood fit

**TODO:** This section is very similar to what is written in the support note... May need to put some work into flushing it out so it's not so close to copy-paste The number of predicted signal events in each channel  $c$  and  $m_{jj}$  bin  $b$  can be calculated from the SM predicted signal cross section  $\sigma_{\text{theo}}^{\text{tot}}$ , the total integrated luminosity  $\mathcal{L}$ , the signal acceptance  $\mathcal{A}$ , and the efficiency corrections  $\mathcal{C}(\theta)$ , where  $\theta$  represents the set of nuisance parameters that parameterize the effects of each systematic uncertainty on the signal and background expectations. The acceptance and efficiency corrections will be covered in more detail in Section 5.4.2.

$$N_{cb}^{\text{sig}}(\theta) = \sigma_{\text{theo}}^{\text{tot}} \mathcal{A}_b \mathcal{C}_b(\theta) \mathcal{L} \quad (5.14)$$

A signal strength parameter  $\mu$  is defined as the ratio of the measured cross section to the SM predicted cross section. The expected number of events in a given channel and bin can then be expressed as the sum of the estimated background ( $N_{cb}^{\text{bkg}}(\theta)$ ) and the number of predicted signal events scaled by  $\mu$ :

$$\begin{aligned} N_{cb}^{\text{exp}}(\theta) &= \mu N_{cb}^{\text{sig}}(\theta) + N_{cb}^{\text{bkg}}(\theta) \\ &= \mu \sigma_{\text{theo}}^{\text{tot}} \mathcal{A}_b \mathcal{C}_b(\theta) \mathcal{L} + N_{cb}^{\text{bkg}}(\theta) \end{aligned} \quad (5.15)$$

The nuisance parameters are constrained by Gaussian probability distribution functions, and the normalization of the  $WZ$  background mentioned in Section 5.3.1 is included in the fit as a free

1432 parameter. The expected yields for signal and background processes are adjusted by the set of  
 1433 nuisance parameters within the constraints of the systematic uncertainties. The yields after the fit  
 1434 correspond to the value that best matches the observed data.

1435 The number of events per channel and bin after the fit can be written as a sum of the predicted  
 1436 event yields for each sample  $s$ :

$$\nu_{cb}(\phi, \theta, \gamma_{cb}) = \gamma_{cb} \sum_s [\eta_{cs}(\theta) \phi_{cs}(\theta) \lambda] h_{cbs}(\theta) \quad (5.16)$$

1437 In this equation, the fitted number of events in a given channel and bin is obtained by weighting  
 1438 the histogram of predicted yields  $h_{cbs}$  by the product of a given luminosity  $\lambda$  and any normalization  
 1439 factors  $\phi_{cs}$  that may be given for each channel and sample. The input histogram and the normaliza-  
 1440 tion factors may depend on the nuisance parameters  $\theta$  taking into account sources of systematic  
 1441 uncertainty. Uncertainties on the normalization factors  $\eta_{cs}(\theta)$  are also included. Finally, bin-by-bin  
 1442 scale factors  $\gamma_{cb}$  are included to parameterize the statistical uncertainties of the MC predictions.

1443 The binned likelihood function is given by a product of Gaussian functions for the luminosity  
 1444 and for the background uncertainties and a product of Poisson functions for the number of observed  
 1445 events in each bin and channel:

$$L(\mu|\theta) = \mathcal{G}(\mathcal{L}|\theta_{\mathcal{L}}, \sigma_{\mathcal{L}}) \cdot \prod_c \prod_b \mathcal{P}(N_{cb}^{\text{meas.}}|\nu_{cb}(\mu)) \prod_p \mathcal{G}(\theta_p^0|\theta_p) \quad (5.17)$$

1446 where  $\mathcal{G}$  and  $\mathcal{P}$  are the Gaussian and Poisson functions, respectively. As before,  $\mathcal{L}$  represents the  
 1447 integrated luminosity with uncertainty  $\sigma_{\mathcal{L}}$  and associated nuisance parameter  $\theta_{\mathcal{L}}$ . The number of  
 1448 measured events in a given bin and channel is represented by  $N_{cb}^{\text{meas.}}$ , and  $\nu_{cb}(\mu)$  is the predicted  
 1449 number of events defined in Equation 5.16 expressed as a function of the signal strength  $\mu$ . Finally,  
 1450 the set of nuisance parameters  $\theta$  and any auxiliary measurements used to constrain them  $\theta^0$  are  
 1451 multiplied for each parameter  $p$ .

1452 The profile likelihood ratio is defined as

$$q_{\mu} = -2 \ln \frac{L(\mu, \hat{\theta}_{\mu})}{L(\hat{\mu}, \hat{\theta})} \quad (5.18)$$

1453 with  $\hat{\mu}$  and  $\hat{\theta}$  as the unconditional maximum likelihood estimates and  $\hat{\theta}$  as the conditional maximum  
 1454 likelihood estimate for a given value of  $\mu$ . The fitted signal strength  $\hat{\mu}$  is obtained by maximizing  
 1455 the likelihood function with respect to all parameters. The compatibility of the observed data  
 1456 with the background-only hypothesis can then be calculated by setting  $\mu = 0$ . Observation of the  
 1457  $W^{\pm}W^{\pm}jj$  EWK process is claimed if the data is found to be inconsistent with the background-only  
 1458 hypothesis by more than  $5\sigma$ .

1459 **5.4.2 Definition of the fiducial volume**

1460 Before extracting the cross section, it is necessary to define the fiducial volume, or the phase space  
 1461 of measureable events. It is a subset of the total phase space defined by selection requirements  
 1462 designed to mirror those applied in the analysis as closely as possible. The selection criteria for the  
 1463 fiducial volume are listed in Table 5.18.

Fiducial region selection	
Lepton selection	Two prompt leptons ( $e, \mu$ ) $p_T > 27$ GeV and $ \eta  < 2.5$ for both leptons Both leptons with the same electric charge Dilepton invariant mass $m_{ll} > 20$ GeV Dilepton separation $\Delta R(ll) > 0.3$
Missing transverse energy	Two neutrino system with $p_T^{\nu\nu} > 30$ GeV
Jet selection	At least two jets Leading jet $p_T > 65$ GeV Subleading jet $p_T > 35$ GeV Leading and subleading jet $ \eta  < 4.5$ Jet-lepton separation $\Delta R(l, j) > 0.3$ Dijet invariant mass $m_{jj} > 500$ GeV Dijet separation $\Delta y_{jj} > 2.0$

Table 5.18: Definition of the fiducial volume.

1464 In MC simulations, the total phase space is generated, providing the total theoretical cross section  
 1465  $\sigma_{\text{theo}}^{\text{tot}}$  and the total number of signal events  $\mathcal{N}_{\text{sig}}^{\text{tot}}$ <sup>16</sup>. After applying the fiducial selection at truth  
 1466 level, the total number of signal events in the fiducial region  $\mathcal{N}_{\text{sig}}^{\text{fid}}$  is obtained. An acceptance factor  
 1467  $\mathcal{A}$  is used to represent the efficiency of events falling in the fiducial region at truth level:

$$\mathcal{A} = \frac{\mathcal{N}_{\text{sig}}^{\text{fid}}}{\mathcal{N}_{\text{sig}}^{\text{tot}}} \quad (5.19)$$

1468 A correction factor  $\mathcal{C}$  is also necessary to translate from the truth level fiducial volume to the  
 1469 reconstruction level signal region and is defined in terms of the number of reconstruction level MC  
 1470 events in the signal region  $N_{\text{sig}, \text{MC}}^{\text{SR}}$ :

$$\mathcal{C} = \frac{N_{\text{sig}, \text{MC}}^{\text{SR}}}{\mathcal{N}_{\text{sig}}^{\text{fid}}} \quad (5.20)$$

1471 Since the fit is binned in  $m_{jj}$ , the acceptance and efficiency correction factors need to be as well.  
 1472 Therefore,  $\mathcal{A}_i$  and  $\mathcal{C}_{ij}$  are written in terms of truth  $m_{jj}$  bins  $i$  and reconstruction  $m_{jj}$  bins  $j$ . A  
 1473 graphical representation of these regions and the use of the acceptance and correction factors can  
 1474 be seen in Figure 5.28.

<sup>16</sup>For the purpose of clarity, the number of events at truth level is represented by a script  $\mathcal{N}$ , and the number of events at reconstruction level uses a regular  $N$ .

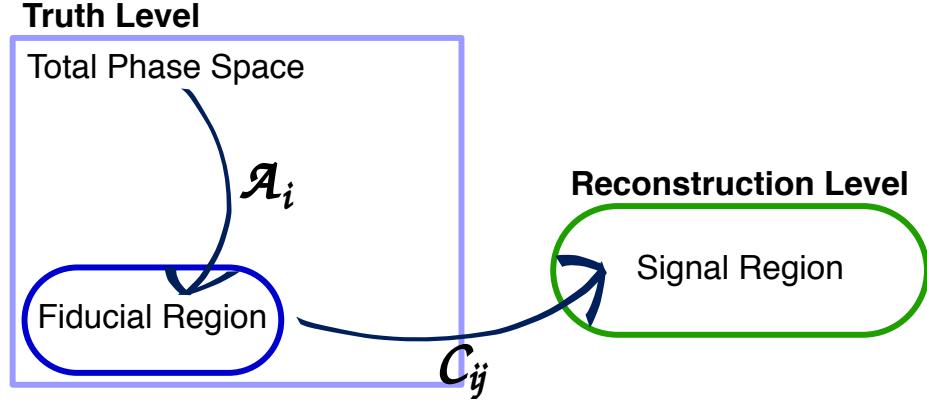

Figure 5.28: Visual representation of the different kinematic regions relevant to the cross section measurement. The acceptance factor  $\mathcal{A}$  converts from the truth level total phase space to the truth level fiducial region, and the efficiency correction  $\mathcal{C}$  translates the fiducial region into the reconstruction level signal region.

#### 1475 5.4.3 Cross section extraction

1476 The  $W^\pm W^\pm jj$  EWK fiducial cross section is measured using the signal strength parameter  $\mu$  that is  
 1477 determined by the maximum likelihood fit. This parameter is dependent on the nuisance parameters  
 1478  $\theta$  and can be written explicitly in terms of the measured and theoretical cross sections as:

$$\mu(\theta) = \frac{\sigma_{\text{meas}}^{\text{SR}}}{\sigma_{\text{theo}}^{\text{SR}}} \quad (5.21)$$

1479 In the simple case with only one bin, the equation for the total number of expected events in the  
 1480 signal region first introduced in Equation 5.15 can be written as:

$$N_{\text{exp}}^{\text{SR}}(\theta) = \mu(\theta) \cdot \sigma_{\text{theo}}^{\text{tot}} \cdot \mathcal{L} \cdot \mathcal{A} \cdot \mathcal{C}(\theta) + N_{\text{bkg}}^{\text{SR}}(\theta) \quad (5.22)$$

1481 with the non-binned versions of  $\mathcal{A}$  and  $\mathcal{C}$  defined in Equations 5.19 and 5.20, respectively.

1482 If the measured fiducial cross section is written as:

$$\sigma_{\text{meas}}^{\text{fid}} = \mu \cdot \mathcal{A} \cdot \sigma_{\text{theo}}^{\text{tot}} \quad (5.23)$$

1483 then Equation 5.22 can be rearranged to read:

$$\sigma_{\text{meas}}^{\text{fid}} = \frac{N_{\text{exp}}^{\text{SR}}(\theta) - N_{\text{bkg}}^{\text{SR}}(\theta)}{\mathcal{L} \cdot \mathcal{C}(\theta)} \quad (5.24)$$

1484 The measured fiducial cross section can finally be rewritten in terms of  $\hat{\mu}$ , which is the best estimator  
 1485 of the signal strength as extracted from the fit:

$$\begin{aligned} \sigma_{\text{meas}}^{\text{fid}} &= \hat{\mu}(\theta) \cdot \sigma_{\text{theo}}^{\text{tot}} \cdot \mathcal{A} \\ &= \hat{\mu}(\theta) \cdot \sigma_{\text{theo}}^{\text{fid}} \end{aligned} \quad (5.25)$$

1486 In practice, however, the cross section is not extracted from a single bin, and Equation 5.22  
1487 becomes for a single channel in truth and reconstruction level  $m_{jj}$  bins  $i$  and  $j$ , respectively:

$$N_{\text{exp}}^{\text{SR}}(\theta) = \mu(\theta) \cdot \sigma_{\text{theo}}^{\text{tot}} \cdot \mathcal{L} \cdot \sum_i \mathcal{A}_i \cdot \sum_j \mathcal{C}_{ij} + \sum_j N_{\text{bkg},j}^{\text{SR}}(\theta) \quad (5.26)$$

1488 where now the binned versions of  $\mathcal{A}_i$  and  $\mathcal{C}_{ij}$  are used. This equation can be extended to include all  
1489 the analysis channels by increasing the number of bins  $i$  and  $j$ . Additionally, it can be shown that  
1490 Equation 5.25 holds for this more complex case as well [26], provided care is taken to ensure that  
1491 all the uncertainties are handled properly.

## 1492 5.5 Summary of uncertainties

1493 Systematic uncertainties enter the final fit as nuisance parameters which can impact the estimated  
1494 signal and background yields and the shapes of the  $m_{jj}$  distributions. These uncertainties can arise  
1495 from the experimental methods or from the theoretical calculations used in the analysis. This section  
1496 summarizes the systematic uncertainties; the experimental uncertainties are detailed in Section 5.5.1,  
1497 and the theoretical uncertainties are covered in Section 5.5.2. The impacts of the systematic uncer-  
1498 tainties on the final cross section measurement are summarized in Table 5.19.

Source	Impact [%]
Reconstruction	$\pm 4.0$
Electrons	$\pm 0.5$
Muons	$\pm 1.2$
Jets and $E_{\text{T}}^{\text{miss}}$	$\pm 2.8$
$b$ -tagging	$\pm 2.0$
Pileup	$\pm 1.5$
Background	$\pm 5.0$
Misid. leptons	$\pm 3.9$
Charge misrec.	$\pm 0.3$
$WZ$	$\pm 1.3$
$W^\pm W^\pm jj$ QCD	$\pm 2.8$
Other	$\pm 0.8$
Signal	$\pm 3.6$
Interference	$\pm 1.0$
EW Corrections	$\pm 1.3$
Shower, Scale, PDF & $\alpha_s$	$\pm 3.2$
Total	$\pm 7.4$

Table 5.19: Impact of various systematic effects on the fiducial cross section measurement. The impact of a given source of uncertainty is computed by performing the fit with the corresponding nuisance parameter varied up or down by one standard deviation from its nominal value.

1499 **5.5.1 Experimental uncertainties**

1500 Experimental uncertainties include detector effects as well as uncertainties on the background es-  
 1501 timation methods. Sources of systematic uncertainty on the measurement of physics objects are  
 1502 listed in Table 5.20, grouped by the relevant object type. For backgrounds estimated from MC  
 1503 simulations, variations in these sources of uncertainty are propagated through the analysis to obtain  
 1504 the corresponding uncertainties on the event yields. Additional experimental uncertainties include  
 1505 the integrated luminosity, the photon conversion rate from Section 5.3.2, and the data driven charge  
 1506 misidentification and fake lepton background estimations from Sections 5.3.3 and 5.3.4.5, respec-  
 1507 tively.

1508 The largest sources of experimental uncertainty on the MC estimations come from the jet-related  
 1509 uncertainties and the  $b$ -tagging efficiency, while the largest uncertainty on the background estimation  
 1510 comes from the fake factor. The effects of the uncertainties on the  $W^\pm W^\pm jj$  EWK signal and the  
 1511 dominant MC estimated background,  $WZ$ , are listed in Tables 5.21 and 5.22, respectively. Since  
 1512 the overall contributions from other processes estimated with MC are small, the uncertainties on  
 1513 these backgrounds have a lesser impact on the final measurement; these tables can be found in  
 1514 Appendix B.1.

Experimental uncertainties

Table 5.22: Impact of experimental uncertainties for the  $WZ$  process in all channels.

### 1515 5.5.2 Theoretical uncertainties

1516 It is also necessary to consider uncertainties on the theoretical predictions in the fiducial region. They  
 1517 include the choice of PDF set, the value of the strong coupling constant  $\alpha_s$ , the renormalization  
 1518 scale  $\mu_R$ , the factorization scale  $\mu_F$ , and the parton showering. The size of these uncertainties are  
 1519 measured by generating new samples with variations in a chosen parameters and comparing them  
 1520 to samples using the nominal choice of the parameter. Internal variations on the PDF sets or using  
 1521 a different set entirely results in a relative uncertainty of up to 2.25% on the nominal sample. The  
 1522 impact from varying  $\alpha_s$  is very small, on the order of < 0.01%. The factorization and renormalization  
 1523 scales are independently varied between 0.5-2.0 from their nominal values of 1.0. This results in  
 1524 relative uncertainties on the prediction of up to 15%. Finally, varying the parameters in the parton  
 1525 showering results in up to 8% uncertainty.

#### 1526 5.5.2.1 Uncertainties from EWK-QCD interference

1527 As mentioned in Section 5.0.2,  $W^\pm W^\pm jj$  production consists of both EWK processes. The two  
 1528 production modes cannot be naively separated due to cross terms in the matrix element calculation.  
 1529 These cross terms are referred to as *interference* terms. Since the  $W^\pm W^\pm jj$  EWK production is  
 1530 the focus of the analysis, and the signal region is designed to preferentially select those events, it is  
 1531 important to measure the size of the EWK-QCD interference contributions.

1532     The interference effects are estimated using the `MadGraph` MC generator, as it has a feature that  
 1533   allows direct modelling of the interference term. This allows four samples to be generated:

- 1534     1. Inclusive: All available diagrams are used in the matrix element calculation  
 1535     2. EWK only: Only EWK diagrams ( $\mathcal{O}(\alpha_{\text{EWK}}) = 4$ ) are used  
 1536     3. QCD only: Only QCD diagrams ( $\mathcal{O}(\alpha_s) = 2 \otimes \mathcal{O}(\alpha_{\text{EWK}}) = 2$ ) are used  
 1537     4. Interference: Only the interference terms are used

1538   A minimal set of generator level cuts, listed in Table 5.23, is applied in order to avoid biasing the  
 1539   sample towards either production mode. The cross sections for each of the four channels can be  
 1540   found in Table 5.24. The size of the interference is found to be approximately 6% of the total cross  
 1541   section and is taken as a systematic uncertainty.

Generator level cuts
$\Delta\eta_{jj} < 10$
Jet $p_{\text{T}} > 20$ GeV
$M_{jj} > 10$ GeV

Table 5.23: The set of generator level cuts used for generating the interference samples with `MadGraph`.

Sample	$\sigma$ (fb)
Inclusive	$3.646 \pm 0.0012$
EWK only	$2.132 \pm 0.0005$
QCD only	$1.371 \pm 0.0008$
Interference	$0.227 \pm 0.0002$

Table 5.24: Cross sections for each different  $W^\pm W^\pm jj$  production mode (inclusive, EWK only, QCD only, and interference only) generated using `MadGraph`. The cross sections are calculated using a minimal set of generator level cuts from events where the  $W$  decays to a muon.

## 1542   5.6 Results

1543   After running the full analysis chain, the event yields in the signal region, low- $m_{jj}$  control region,  
 1544   and  $WZ$  control region as well as associated nuisance parameters representing the uncertainties are  
 1545   passed to the maximum likelihood fit. From this fit, the normalization factor for the  $WZ$  control  
 1546   region  $\mu_{WZ}$  and the signal strength parameter in the signal region  $\mu_{\text{obs}}$  are determined, and the  
 1547   predicted yields in each input bin have been shifted according to the process detailed in Section 5.4.1.

1548 The  $WZ$  normalization factor is measured to be:

$$\mu_{WZ} = 0.88^{+0.07}_{-0.07}(\text{stat})^{+0.31}_{-0.21}(\text{theory})^{+0.22}_{-0.11}(\text{sys}) \quad (5.27)$$

1549 and is constrained primarily by the number of data events in the  $WZ$  control region. The observed  
 1550 signal strength of  $W^\pm W^\pm jj$  EWK production, defined in Equation 5.21, is extracted from the fit  
 1551 and measured with respect to the prediction of the **SHERPA v2.2.2** MC generator:

$$\mu_{\text{obs}} = 1.45^{+0.25}_{-0.24}(\text{stat})^{+0.06}_{-0.08}(\text{theory})^{+0.27}_{-0.22}(\text{sys}) \quad (5.28)$$

1552 This corresponds to a rejection of the background-only hypothesis with a significance of  $6.9\sigma$ .

1553 The observed number of data events are compared to the predicted signal and background yields  
 1554 in the signal region in Table 5.25 before applying the fit and in Table 5.26 after the fit. The  $m_{jj}$   
 1555 distributions for data and prediction are shown in Figure 5.29 after the fit, and the fitted event  
 1556 yields in the low- $m_{jj}$  and  $WZ$  control regions are shown in Figure 5.30. Additional distributions  
 1557 can be found in Appendix B.

Data	10	4	44	28	25	11	122

Table 5.25: Table of the data and prediction event yields in the signal region before the fit. Numbers are shown for the six lepton flavor and charge channels and for all channels combined. Here the  $WZ$  background yields are normalized to the data in the  $WZ$  control region. The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from  $V\gamma$  production and electron charge misidentification are combined in the “ $e/\gamma$  conversions” category. Finally,  $ZZ$ ,  $VVV$ , and  $t\bar{t}V$  backgrounds are combined in the “Other prompt” category.

1558 The last ingredient necessary to measure the  $W^\pm W^\pm jj$  EWK cross section is the theory predicted  
 1559 cross section in the fiducial region defined in Table 5.18. **SHERPA v2.2.2** is used for the calculation,  
 1560 and the cross section in the total generator phase space is  $40.81 \pm 0.05$  fb, and the fiducial cross section  
 1561 is  $2.01 \pm 0.02$  fb. This corresponds to an acceptance factor of  $\mathcal{A} = 0.0493 \pm 0.0002$ . Uncertainties on  
 1562 the simulation are estimated using variations of the scale, parton shower, and PDF set. The final  
 1563 prediction used in the cross section measurement including uncertainties from Section 5.5.2 is:

$$\sigma_{\text{SHERPA}}^{\text{fid}} = 2.01 \pm 0.02(\text{stat})^{+0.29}_{-0.23}(\text{scale})^{+0.16}_{-0.02}(\text{parton shower})^{+0.05}_{-0.03}(\text{PDF}) \text{ fb} \quad (5.29)$$

	$e^+e^+$	$e^-e^-$	$\mu^+e^+$	$\mu^\pm e^\pm m$	$\mu^+\mu^+$	$\mu^-\mu^-$	combined
$WZ$	$1.49 \pm 0.30$	$1.10 \pm 0.26$	$11.7 \pm 1.7$	$8.0 \pm 1.3$	$5.0 \pm 0.6$	$3.5 \pm 0.6$	$31 \pm 4$
Non-prompt	$2.2 \pm 1.3$	$1.2 \pm 0.7$	$5.7 \pm 2.8$	$4.5 \pm 1.8$	$0.57 \pm 0.06$	$0.65 \pm 0.14$	$15 \pm 6$
$e/\gamma$ conversions	$1.6 \pm 0.4$	$1.6 \pm 0.5$	$6.3 \pm 1.6$	$4.3 \pm 1.1$	—	—	$13.8 \pm 2.9$
Other prompt	$0.16 \pm 0.04$	$0.14 \pm 0.04$	$0.90 \pm 0.19$	$0.63 \pm 0.13$	$0.39 \pm 0.09$	$0.22 \pm 0.05$	$2.4 \pm 0.5$
$W^\pm W^\pm jj$ QCD	$0.35 \pm 0.13$	$0.15 \pm 0.05$	$2.9 \pm 1.0$	$1.2 \pm 0.4$	$1.8 \pm 0.6$	$0.76 \pm 0.25$	$7.2 \pm 2.4$
Expected background	$5.8 \pm 1.5$	$4.1 \pm 1.1$	$27 \pm 4$	$18.7 \pm 2.6$	$7.7 \pm 0.8$	$5.1 \pm 0.6$	$69 \pm 7$
$W^\pm W^\pm jj$ EWK	$5.6 \pm 1.0$	$2.2 \pm 0.4$	$24 \pm 5$	$9.4 \pm 1.8$	$13.5 \pm 2.5$	$5.2 \pm 1.0$	$60 \pm 11$
Data	10	4	44	28	25	11	122

Table 5.26: Table of the data and prediction event yields in the signal region after the fit. Numbers are shown for the six lepton flavor and charge channels and for all channels combined. The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from  $V\gamma$  production and electron charge misidentification are combined in the “ $e/\gamma$  conversions” category. Finally,  $ZZ$ ,  $VVV$ , and  $t\bar{t}V$  backgrounds are combined in the “Other prompt” category.

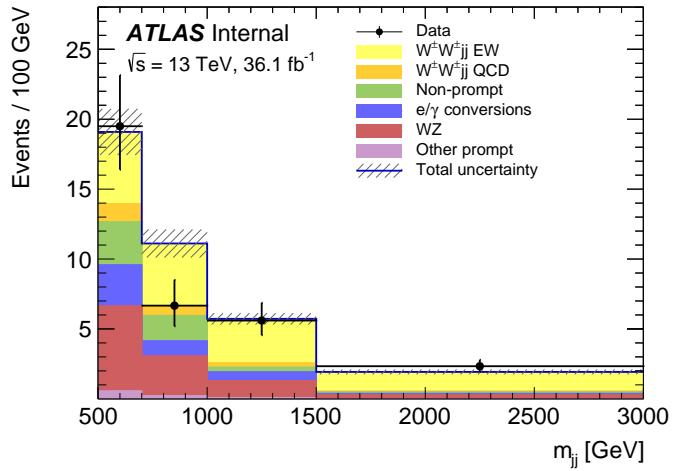

Figure 5.29: The dijet invariant mass  $m_{jj}$  distributions for data and predicted signal and background in the signal region after the fit. The shaded band represents the statistical and systematic uncertainties added in quadrature. Note that the bins have been scaled such that they represent the number of events per  $100 \text{ GeV}$  in  $m_{jj}$ . The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from  $V\gamma$  production and electron charge misidentification are combined in the “ $e/\gamma$  conversions” category. Finally,  $ZZ$ ,  $VVV$ , and  $t\bar{t}V$  backgrounds are combined in the “Other prompt” category.

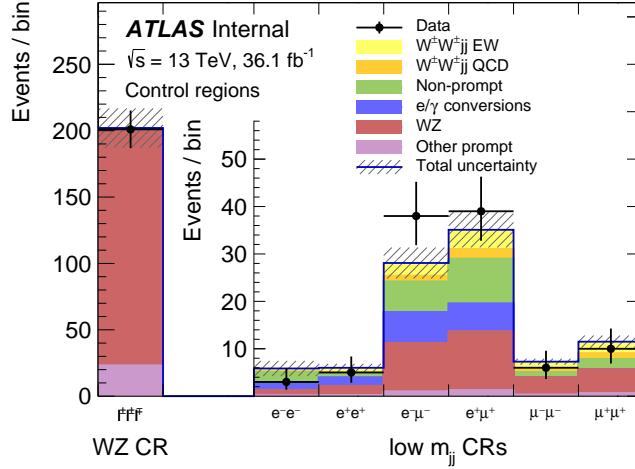

Figure 5.30: The event yields for data and predicted signal and background in the  $WZ$  and low- $m_{jj}$  control regions after the fit. The shaded band represents the statistical and systematic uncertainties added in quadrature. The background estimations from the fake factor are included in the “Non-prompt” category, and backgrounds from  $V\gamma$  production and electron charge misidentification are combined in the “ $e/\gamma$  conversions” category. Finally,  $ZZ$ ,  $VVV$ , and  $t\bar{t}V$  backgrounds are combined in the “Other prompt” category.

1564 Combining this **SHERPA** prediction with the measured signal strength  $\mu_{\text{obs}}$  from Equation 5.28,  
 1565 the measured fiducial cross section  $\sigma_{\text{meas}}^{\text{fid}}$  can be calculated using Equation 5.25:

$$\sigma_{\text{meas}}^{\text{fid}} = 2.91^{+0.51}_{-0.47}(\text{stat})^{+0.12}_{-0.16}(\text{theory})^{+0.24}_{-0.23}(\text{sys})^{+0.08}_{-0.06}(\text{luminosity}) \text{ fb} \quad (5.30)$$

1566 A plot comparing the measured fiducial cross section to two theoretical calculations is shown in  
 1567 Figure 5.31. The measured value is compared to the **SHERPA v2.2.2** prediction used to calculate  
 1568  $\mu_{\text{obs}}$  as well as to **POWHEG-BOX v2**. As mentioned in Section 5.1.1, this **POWHEG** sample does not  
 1569 include the resonant triboson diagrams and is only used here for a visual comparison.

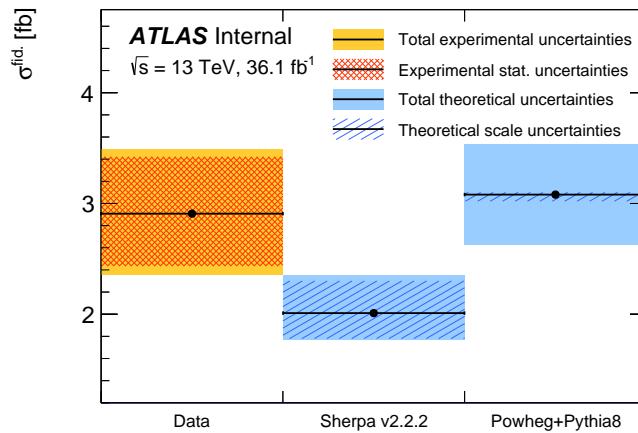

Figure 5.31: Comparison of the measured  $W^\pm W^\pm jj$  EWK fiducial cross section with theoretical calculations from **SHERPA v2.2.2** and **POWHEG-BOX v2**. The light orange band represents the total experimental uncertainty on the measured value, and the dark orange hashed band is the statistical uncertainty. For the simulations, the light blue band represents the total theoretical uncertainty, and the dark blue hashed band are the scale uncertainties. The theory predictions do not include the interference between the EWK and QCD production.

1570

## CHAPTER 6

1571

# Prospects for same-sign $WW$ at the High Luminosity LHC

1572

1573 On December 3, 2018, Run 2 of the LHC officially ended, and the collider was shut down to begin  
1574 the first of two scheduled extended maintenance periods [62]. During these two long shutdowns,  
1575 the Phase-I and Phase-II upgrades of the LHC and ATLAS will occur in order to prepare for the  
1576 High-Luminosity LHC (HL-LHC) which is scheduled to begin operation in 2026 [63].

1577 The HL-LHC is planned to run at a center-of-mass energy of  $\sqrt{s} = 14$  TeV with an instantaneous  
1578 luminosity of  $\mathcal{L} = 5 \times 10^{34}$  cm $^{-2}$ s $^{-1}$  with up to 200 collisions per beam-crossing. Over the course  
1579 of operation, the HL-LHC is expected to collect a total integrated luminosity of  $\mathcal{L} = 3000$  fb $^{-1}$  by  
1580 2035 [64]. **TODO: Compare to current LHC numbers?**

1581 These run conditions will be much harsher than what ATLAS has experienced so far, and there  
1582 are several upgrades planned for the detector to operate in the high luminosity environment. Most  
1583 notably, the entire ID will be replaced with an all-silicon tracker which will extend the coverage from  
1584  $|\eta| \leq 2.7$  up to  $|\eta| \leq 4.0$ . This will allow for reconstruction of charged particle tracks which can  
1585 in turn be matched to clusters in the calorimeters for electron identification or forward jet tagging  
1586 [65].

1587 The upgraded detector, the higher beam energy, and the increased volume of data to be collected  
1588 provides the opportunity to measure rarer processes with a much higher precision than what was  
1589 possible in Run 1. Same-sign  $W^\pm W^\pm jj$  production, is one such process. With greater statistics,  
1590 the accuracy of the cross section measurement can be improved over the 13 TeV analysis detailed in  
1591 Chapter 5, and it also will allow for more detailed physics studies, such as measuring the polarization  
1592 of the  $W$  bosons. A measurement of the longitudinal polarization of the scattered  $W$  bosons has

1593 not yet been possible, but it remains of great interest due to its sensitivity to electroweak symmetry  
 1594 breaking [66]. The analysis detailed in this chapter is based off of the 2018 ATLAS HL-LHC  
 1595  $W^\pm W^\pm jj$  prospects study [67] which is itself an extension of the 2017 ATLAS study [68]. **TODO:**  
 1596 mention CMS's study + yellow report?

### 1597 6.0.1 Analysis Overview

1598 The experimental signature of interest is identical to the 13 TeV analysis: two prompt leptons (either  
 1599 electrons or muons) with the same charge, missing transverse energy, and two high energy, forward  
 1600 jets. These jets are again required to have a large angular separation and a high combined invariant  
 1601 mass to preferentially select EWK- over QCD-produced  $W^\pm W^\pm jj$  events.

1602 Background processes are again similar to the 13 TeV analysis and are summarized again here.  
 1603 The dominant source of prompt background from  $WZ+jets$  events where both bosons decay lepton-  
 1604ically. If the lepton from the  $Z$ -decay with opposite charge from the  $W$  falls outside of the detector  
 1605 acceptance or is not identified, the remainder could appear to be a  $W^\pm W^\pm jj$  signal event. To a  
 1606 lesser extent,  $ZZ+jets$  events can enter the signal region in much the same way provided two lep-  
 1607 tons are “lost”. Other prompt sources include  $t\bar{t}+V$  and multiple parton interactions, however  
 1608 these processes do not contribute much. These prompt backgrounds are expected to contribute  
 1609 less than in Run 2 with the addition of forward tracking in the upgraded ATLAS detector. Jets  
 1610 mis-reconstructed as leptons or leptons from hadronic decays (such as  $t\bar{t}$  and  $W+jets$  production)  
 1611 comprise the non-prompt lepton background. Lastly, events with two prompt, opposite-charge elec-  
 1612 trons can appear as a same-sign event provided one of the electrons is mis-reconstructed as the  
 1613 wrong charge.

1614 In this analysis, the EWK production of  $W^\pm W^\pm jj$  is studied in the context of the planned  
 1615 HL-LHC run conditions and upgraded ATLAS detector. An optimized event selection (referred to  
 1616 as the *optimized selection*) is also explored in an effort to gain increased signal significance over  
 1617 the *default selection*. The cross section of the inclusive EWK production is measured for both the  
 1618 default and optimized selections, and the extraction of the longitudinal scattering significance is  
 1619 measured with the optimized selection.

## 1620 6.1 Theoretical motivation

1621 The theoretical motivation for studying the ssWW process—and VBS in general—is detailed in Sec-  
 1622 tion 5.0.2. Since it is specifically the scattering of *longitudinally polarized* vector bosons that violates

1623 unitarity without a SM Higgs boson, a direct measurement of this cross section will be very useful  
 1624 for understanding how the Higgs unitarizes the process [66].

### 1625 6.1.1 Experimental sensitivity to longitudinal polarization

1626 **TODO:** mention that since there are so many polarization possibilities, a large integrated luminosity  
 1627 is needed to measure just one of them individually There are three possible polarization states for  
 1628 a massive vector boson: two transverse (+ or -) and one longitudinal (0). Therefore, in a system  
 1629 with two  $W$  bosons, the overall polarization can be purely longitudinal (00), purely transverse (++,  
 1630 --, and +-), or mixed (+0 and -0). The three combinations will be referred to as  $LL$ ,  $TT$ , and  
 1631  $LT$  respectively.

1632 In order extract the longitudinal scattering component, it is necessary to find variables that  
 1633 distinguish the  $LL$  from the  $TT$  and  $LT$ . Several were studied, and those with the best discriminating  
 1634 power between the polarizations are the leading and subleading lepton  $p_T$  as well as the azimuthal  
 1635 separation ( $|\Delta\phi_{jj}|$ ) of the two VBS jets. The  $LL$  events prefer lower  $p_T$  for both signal leptons  
 1636 (see Figure 6.1), which motivates keeping cuts on these quantities as low as possible in the event  
 1637 selection. In the case of  $|\Delta\phi_{jj}|$ , the  $LL$  events generally had a larger dijet separation (see Figure 6.2),  
 1638 and this variable is used in a binned likelihood fit to extract the longitudinal scattering significance.

## 1639 6.2 Monte Carlo samples

1640 As no real HL-LHC data will be available for many years, all signal and background processes are  
 1641 modeled using MC simulations generated at  $\sqrt{s} = 14$  TeV, with the event yields scaled to the  
 1642 anticipated HL-LHC integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . The MC samples used in the analysis  
 1643 are generated at particle-level and have not been run through the typical full simulation of the  
 1644 ATLAS detector. Instead, smearing functions derived from a **GEANT4** simulation of the upgraded  
 1645 ATLAS detector are used to estimate detector effects such as momentum resolution. In addition,  
 1646 pileup events are fully simulated. The MC samples used in this analysis are summarized in Table 6.1.

1647 The signal sample consists of both VBS and non-VBS electroweak (EWK)  $W^\pm W^\pm jj$  production,  
 1648 and it is simulated with the **Madgraph5\_aMC@NLO** generator using the NNPDF3.0 PDF set and in-  
 1649 terfaced with **PYTHIA v8** [69] for hadronization and parton showering. To study the longitudinal  
 1650 polarization more directly, two additional **Madgraph5\_aMC@NLO**  $W^\pm W^\pm jj$  samples are used: one  
 1651 containing only the longitudinal contribution (LL) and a second containing the transverse (TT) and  
 1652 mixed (LT) contributions.

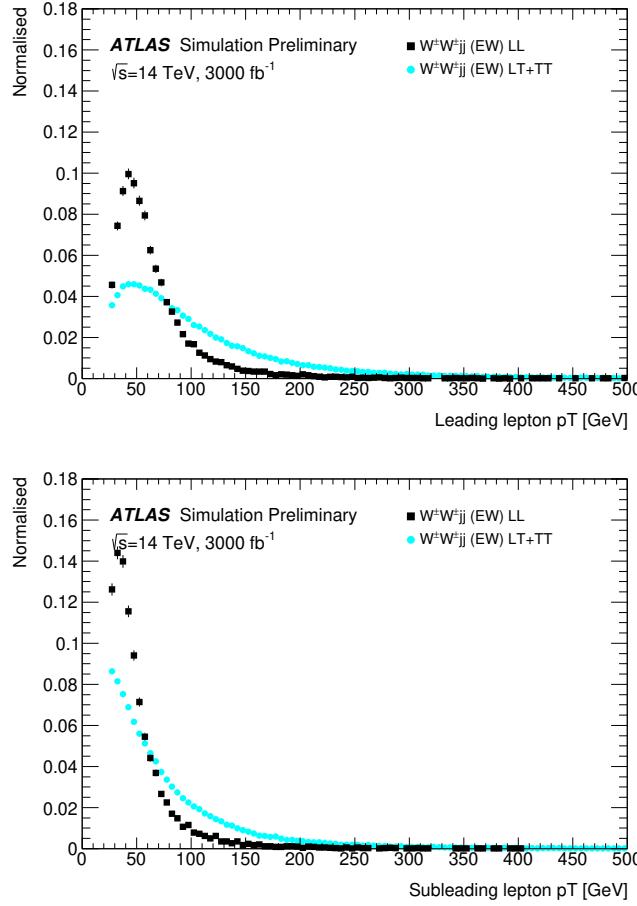

Figure 6.1: Comparison of the leading (top) and subleading (bottom) lepton  $p_T$  distributions for purely longitudinal (LL, black) and mixed polarization (LT+TT, cyan)  $W^\pm W^\pm jj$  events.

1653 There are many other processes that can produce the same final state as the  $W^\pm W^\pm jj$  and  
 1654 must also be accounted for using MC simulations.  $WZ$  events are generated using **SHERPA v2.2.0**,  
 1655 which includes up to one parton at NLO in the strong coupling constant and up to three addi-  
 1656 tional partons at LO. Both EWK and QCD production are included in these samples.  $ZZ$  and  
 1657 triboson  $VVV$  ( $V = W, Z$ ) events are generated using **SHERPA v2.2.2** with up to two additional  
 1658 partons in the final state. For the triboson backgrounds, the bosons can decay leptonically or  
 1659 hadronically.  $W+jets$  backgrounds are generated for electron, muon, and tau final states at LO  
 1660 with **Madgraph5\_aMC@NLO** and the **NNPDF3.0** set with showering from **PYTHIA v8**.  $Z+jets$  events are  
 1661 produced using **POWHEG-BOX v2** and the **CT10** PDF set interfaced with **PYTHIA v8**. Finally,  $t\bar{t}$  and  
 1662 single-top events are generated using **POWHEG-BOX** with showering from **PYTHIA v6**.

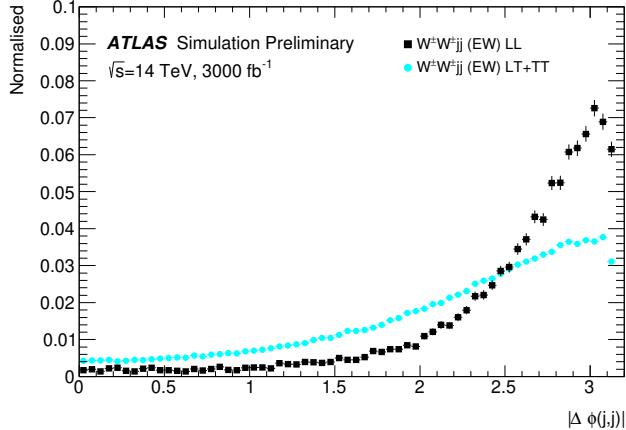

Figure 6.2: Comparison of the azimuthal dijet separation ( $|\Delta\phi_{jj}|$ ) for purely longitudinal (LL, black) and mixed polarization (LT+TT, cyan)  $W^\pm W^\pm jj$  events.

Process	Generator	Comments
$W^\pm W^\pm jj$ (EWK)	Madgraph5_aMC@NLO	Signal sample
$W^\pm W^\pm jj$ (QCD)	Madgraph5_aMC@NLO	
$W^\pm W^\pm jj$ (LL)	Madgraph5_aMC@NLO	Pure longitudinal polarization sample
$W^\pm W^\pm jj$ (TT+LT)	Madgraph5_aMC@NLO	Mixed and transverse polarization sample
Diboson	SHERPA v2.2.0	$WZ$ events
	SHERPA v2.2.2	$ZZ$ events
Triboson	SHERPA v2.2.2	
$W+jets$	Madgraph5_aMC@NLO	
$Z+jets$	POWHEG-BOX v2	
$t\bar{t}$	POWHEG-BOX	
Single top	POWHEG-BOS	

Table 6.1: Summary of MC samples used in the analysis.

### 1663 6.3 Background estimations

1664 In this analysis, all background contributions are estimated using MC simulations. Backgrounds such  
 1665 as electron charge misidentification and fake electrons from jets (which are traditionally estimated  
 1666 using data-driven techniques) are estimated using a set of parameterization functions applied to the  
 1667 MC. These functions calculate the probability that an electron is assigned the wrong charge or a  
 1668 jet is mis-reconstructed as an electron parameterized by the  $p_T$  and  $\eta$  of the electron or jet. The  
 1669 probabilities are derived from studies on expected electron performance with the upgraded ATLAS  
 1670 detector [70].

1671 Processes involving two  $W$  and  $Z$  bosons are grouped together as *diboson* backgrounds, with the

exception of  $W^\pm W^\pm jj$  events produced via QCD interactions, which are kept separate. Similarly, all backgrounds with three vector bosons are combined and labeled as *triboson*. Any  $W+jets$  or top events that pass selection and do not contain a fake electron, as well as any  $Z+jets$  events without an electron identified as having its charge misidentified are combined as *other non-prompt* backgrounds.

### 6.3.1 Truth-based isolation

To properly calculate particle isolation, it requires information from several detector subsystems including tracking and calorimeter responses. Since the MC samples used in this analysis have not been run through a full detector simulation, it is not possible to construct the canonical isolation variables used in analyses. At truth-level, this is generally not a serious concern as  $p_T$  signal leptons tend to be well isolated to begin with. However, isolation is one of the most powerful tools for rejecting leptons from non-prompt sources such as top events, which are produced in association with additional nearby particles from  $b$  and  $c$  quark decays. In this analysis, with the absence of any sort of isolation requirement, contributions from top backgrounds (including single top,  $t\bar{t}$  and  $t\bar{t} + V$ ) are more than an order of magnitude higher than expected.

As a result, it is necessary to find one or more quantities that are comparable to the isolation information that is available in fully-simulated samples. Analogues to track- and calorimeter-based isolation variables are constructed by summing the momentum and energy, respectively, of stable truth particles with  $p_T > 1$  GeV within a specified radius of each signal lepton. For the track-based isolation, only charged truth particles are used; both charged and neutral particles (excluding neutrinos) are included for the calorimeter-based isolation. Ultimately, a set of isolation cuts are chosen that are similar to those recommended by ATLAS for Run 2 analyses. The truth-based isolation requirements are listed in Table 6.2.

	Electron Isolation	Muon Isolation
Track-based isolation cone size	$\Delta R < 0.2$	$\Delta R < 0.3$
Track-based isolation requirement	$\sum p_T/p_T^e < 0.06$	$\sum p_T/p_T^\mu < 0.04$
Calorimeter-based isolation cone size	$\Delta R < 0.2$	$\Delta R < 0.2$
Calorimeter-based isolation requirement	$\sum E_T/p_T^e < 0.06$	$\sum E_T/p_T^\mu < 0.15$

Table 6.2: Truth-based isolation requirements for electrons and muons.

The truth-based isolation requirement reduces the top background by over 99%, and the percentage of the total background consisting of top events is reduced from 83% to 2%. Additional details on the truth-based isolation studies are presented in Appendix A.

---

1697 **6.4 Object and event selection**

1698 **6.4.1 Object selection**

1699 Electrons and muons are preselected to have  $p_T > 7$  and  $6$  GeV, respectively, and  $|\eta| \leq 4.0$ . The  
 1700 likelihood of a given lepton to pass the trigger and identification requirements is estimated by  
 1701 calculating an efficiency dependent on the  $p_T$  and  $\eta$  of the lepton. The leptons are also required to  
 1702 pass the isolation criteria detailed in Table 6.2. Jets that have been tagged as a fake electron by the  
 1703 functions described in Section 6.3 are treated as electrons for the purpose of the object selection and  
 1704 are subject to the same criteria. In order to be considered a signal lepton, an additional requirement  
 1705 of  $p_T > 25$  GeV is applied on top of the preselection. The two highest  $p_T$  leptons passing this  
 1706 selection are chosen to be the leading and subleading signal leptons.

1707 Jets are clustered using the anti- $k_t$  algorithm [53] from final-state particles within a radius of  
 1708  $\Delta R = 0.4$  (excluding muons and neutrinos). Jets are required to have  $p_T > 30$  GeV and lie within  
 1709  $|\eta| < 4.5$ , with an additional cut of  $p_T > 70$  GeV for jets above  $|\eta| \geq 3.8$  in order to suppress jets  
 1710 from pileup interactions. Jets overlapping with a preselected electron within  $\Delta R(e, j) < 0.05$  are  
 1711 removed in order to prevent double counting. The two highest  $p_T$  jets are defined as the leading  
 1712 and subleading *tag jets*.

1713 **6.4.2 Event selection**

1714 The default event selection is summarized in Table 6.3 and described here. Exactly two signal  
 1715 leptons are required with the same electric charge and separated from each other by  $\Delta R(l l) > 0.3$ .  
 1716 In order to suppress contributions from Drell-Yan backgrounds, the two signal leptons must have  
 1717 an invariant mass  $m_{ll}$  greater than  $20$  GeV. Additionally, if both signal leptons are electrons, their  
 1718 mass must be at least  $10$  GeV from the  $Z$ -boson mass in order to reduce background from  $Z$ -boson  
 1719 decays<sup>17</sup>. The event is required to have at least  $40$  GeV of missing transverse energy ( $E_T^{\text{miss}}$ ) to  
 1720 account for the two neutrinos from the  $W$  decays. Events with additional preselected leptons are  
 1721 vetoed, which greatly reduces  $WZ$  and  $ZZ$  backgrounds.

1722 Each event must have at least two jets, and both tag jets are required to not overlap with the  
 1723 signal leptons, and there is a veto on events with one or more  $b$ -jets. In order to preferentially select  
 1724 EWK production, the tag jets are also required to have a large separation between them and a large

---

<sup>17</sup>The electron charge misidentification rate in the upgraded ATLAS detector is estimated to be high enough that contributions from  $Z \rightarrow ee$  backgrounds are non-negligible.

<sup>1725</sup> invariant mass. Finally, a cut on the lepton centrality<sup>18</sup>,  $\zeta$ , defined in Equation 6.1 enhances the  
<sup>1726</sup> EWK  $W^\pm W^\pm jj$  signal.

$$\zeta = \min[\min(\eta_{\ell 1}, \eta_{\ell 2}) - \min(\eta_{j 1}, \eta_{j 2}), \max(\eta_{j 1}, \eta_{j 2}) - \max(\eta_{\ell 1}, \eta_{\ell 2})] \quad (6.1)$$

Selection requirement	Selection value
Lepton kinematics	$p_T > 25$ GeV $ \eta  \leq 4.0$
Jet kinematics	$p_T > 30$ GeV for $ \eta  \leq 4.5$ $p_T > 70$ GeV for $ \eta  > 3.8$
Dilepton charge	Exactly two signal leptons with same charge
Dilepton separation	$\Delta R_{l,l} \geq 0.3$
Dilepton mass	$m_{ll} > 20$ GeV
$Z$ boson veto	$ m_{ee} - m_Z  > 10$ GeV (ee-channel only)
$E_T^{\text{miss}}$	$E_T^{\text{miss}} > 40$ GeV
Jet selection	At least two jets with $\Delta R_{l,j} > 0.3$
$b$ jet veto	$N_{b\text{-jet}} = 0$
Dijet separation	$\Delta \eta_{jj} > 2.5$
Trilepton veto	No additional preselected leptons
Dijet mass	$m_{jj} > 500$ GeV
Lepton-jet centrality	$\zeta > 0$

Table 6.3: Summary of the signal event selection.

## <sup>1727</sup> 6.5 Selection optimization

<sup>1728</sup> An upgraded detector along with an increase in center of mass energy and integrated luminosity  
<sup>1729</sup> provides an opportunity to study whether the event selection can be optimized to improve the signal  
<sup>1730</sup> to background ratio.

### <sup>1731</sup> 6.5.1 Random grid search algorithm

<sup>1732</sup> The chosen method for optimizing the event selection is a cut-based algorithm known as the Random  
<sup>1733</sup> Grid Search (RGS) [71]. Consider a simple case of two variables  $x$  and  $y$  chosen to differentiate signal  
<sup>1734</sup> from background. In order to be considered a signal event, a given event would be required to pass  
<sup>1735</sup> a set of selection criteria, called a *cut point*:  $c = \{x > x_c, y > y_c\}$ . A simple method to choose the  
<sup>1736</sup> optimal cut point (i.e. the “best” values of the cuts  $x_c$  and  $y_c$ ) would be to construct an  $n \times m$

---

<sup>18</sup> $\zeta$  is a measurement of whether the two signal leptons lie between the two tagging jets in  $\eta$ , as is preferred by the VBS topology.

1737 rectangular grid in  $x$  and  $y$  consisting of points  $(x_0, y_0), (x_1, y_1), \dots, (x_n, y_m)$ , as in Figure 6.3. One  
 1738 can then choose a cut point  $c_k = \{x > x_i, y > y_j\}$  that maximizes the signal significance as measured  
 1739 by a chosen metric. This would be considered a *rectangular grid search*.

1740 While effective in principle, a rectangular grid search comes with two major drawbacks:

- 1741 1. The algorithm scales exponentially as the number of variables to be optimized increases, as  
 1742 this is effectively increasing the dimensionality of the grid. In the simple case of a square grid  
 1743 with  $N$  bins per variable  $v$ , the number of cut points to be evaluated grows as  $N^v$ .
- 1744 2. Signal and background samples are rarely evenly distributed over the entire grid, resulting  
 1745 in many cut points being sub-optimal and evaluating them would be a waste of computing  
 1746 resources.

1747 To combat these limitations, the RGS algorithm constructs a grid of cut points directly from  
 1748 the signal sample itself. In the two-dimensional example, this means that the variables  $x_i$  and  $y_j$   
 1749 making up the cut point  $c_k = \{x > x_i, y > y_j\}$  take their values directly from a given signal event.  
 1750 This has the benefit of creating a *random grid* of cut points that is biased towards regions of high  
 1751 signal concentration by construction. This reduces the need for exponentially increasing numbers of  
 1752 cut points while ensuring that computing resources are not wasted in regions with few to no signal  
 1753 events. An example of the the two-dimensional random grid is shown in Figure 6.4.

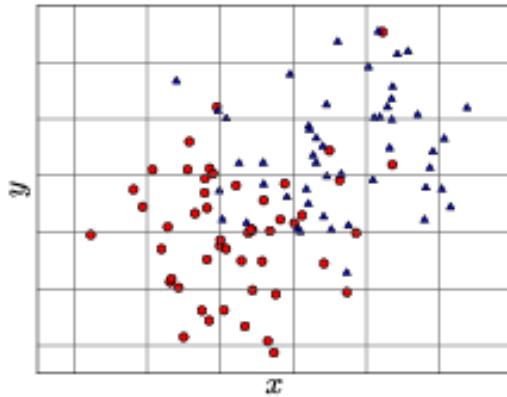

Figure 6.3: A visual representation of a rectangular grid search algorithm. The signal events are the blue triangles, and the red circles are the background events. **TODO: replace with own figure**

1754 Once the random grid of cut points is constructed, the optimal cut point can be chosen using any  
 1755 number of metrics, such as signal to background ratio. For the purpose of the  $W^\pm W^\pm jj$  upgrade

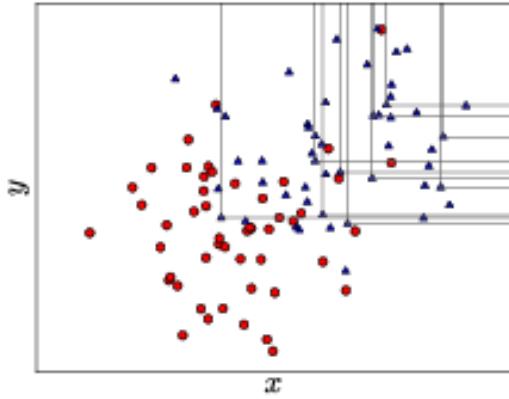

Figure 6.4: A visual representation of a random grid search algorithm. The signal events are the blue triangles, and the red circles are the background events. **TODO: replace with own figure**

study, the optimal cut point is chosen to be the one that maximizes the signal significance  $Z$  as defined in Equation 6.2 [72].

$$Z = \sqrt{2 \left[ (s + b) \ln \left( \frac{s + b}{b_0} \right) + b_0 - s - b \right] + \frac{(b - b_0)^2}{\sigma_b^2}} \quad (6.2)$$

where  $s$  and  $b$  are the number of signal and background events, respectively,  $\sigma_b$  is the total uncertainty on the background, and  $b_0$  is defined as:

$$b_0 = \frac{1}{2} \left( b - \sigma_b^2 + \sqrt{(b - \sigma_b^2)^2 + 4(s + b)\sigma_b^2} \right) \quad (6.3)$$

In the case where the background is known precisely (i.e.  $\sigma_b = 0$ ), Equation 6.2 simplifies to

$$Z = \sqrt{2 \left( b \left[ (1 + s/b) \ln(1 + s/b) - s/b \right] \right)} \quad (6.4)$$

which further reduces to the familiar  $Z = s/\sqrt{b}$  for the case when  $s \ll b$ .

### 6.5.2 Inputs to the optimization

In order to train the RGS, signal and background samples are prepared from events passing the event selection outlined in Table 6.3 up through the  $b$ -jet veto. The signal sample is chosen to be the longitudinally polarized  $W^\pm W^\pm jj$  EWK events, and the transverse and mixed polarizations are treated as background along with  $W^\pm W^\pm jj$  events from QCD interactions and the traditional backgrounds listed in Section 6.3. Splitting the inclusive  $W^\pm W^\pm jj$  EWK events by polarization

1768 allows the optimization to favor the longitudinally polarized events as much as possible, even though  
 1769 they both contribute to the EWK signal.

1770 The following variables are chosen for optimization:

- 1771 • Leading lepton  $p_T$
- 1772 • Dilepton invariant mass ( $m_{ll}$ )
- 1773 • Leading and subleading jet  $p_T$
- 1774 • Dijet invariant mass ( $m_{jj}$ )
- 1775 • Lepton-jet centrality ( $\zeta$ )

1776 Subleading lepton  $p_T$  is omitted as it is desirable to keep the cut value as low as possible due to  
 1777 its sensitivity to the longitudinal polarization (as discussed in Section 6.1.1). Additionally, the dijet  
 1778 separation  $\Delta\eta_{jj}$  was included in the optimization originally, however it was dropped from the list due  
 1779 to the cut value being motivated by differences between EWK and QCD produced  $W^\pm W^\pm jj$  events.

1780 Two additional constraints were imposed when selecting the optimal cut point:

- 1781 1. At least 1000 signal events must survive in order to prevent the optimization from being too  
 1782 aggressive and unnecessarily reducing signal statistics.
- 1783 2. The dijet invariant mass may only vary within a 50 GeV range of the default value (from  
 1784 450 – 550 GeV) due to the cut being physically motivated by the VBS event topology (see  
 1785 Section 5.0.3).

1786 Lastly, the signal significance is calculated without taking into account the uncertainty of the  
 1787 background using Equation 6.4. This is due to the fact that the statistical uncertainties of the fake  
 1788 electron and charge misidentification backgrounds are quite large, owing to poor MC statistics in a  
 1789 few of the samples. If Equation 6.2 were used instead, the optimization will cut unreasonably hard  
 1790 against these backgrounds. Since Monte Carlo statistics is not expected to be a limiting factor when  
 1791 this analysis is performed at the HL-LHC, it is more realistic to simply ignore these large statistical  
 1792 uncertainties for the purpose of the optimization.

### 1793 6.5.3 Results of the optimization

1794 Ultimately, the random grid is constructed from over 38,000 LL-polarized  $W^\pm W^\pm jj$  events in the  
 1795 six variables listed above. After applying the constraints, the optimal cut point reduces the total

background from 9900 to 2310 while reducing the signal from 3489 to 2958. This corresponds to an increase in signal significance from  $Z = 33.26$  to  $Z = 52.63$  as calculated by Equation 6.4. The updates to the event selection are listed in Table 6.4.

The large reduction in the background is primarily a result of the increase in the leading and subleading jet  $p_T$  from 30 GeV to 90 GeV and 45 GeV, respectively. As can be seen in Figure 6.7, this increase removes a significant portion of the backgrounds from jets faking electrons and charge mis-ID. Additionally, the loosening of the lepton-jet centrality cut  $\zeta$  allows more signal events to survive the event selection (see Figure 6.9). Other changes to the event selection are minor and do not individually have a large impact on the signal or background yields.

The full event yields after optimization as well as the cross section measurement are detailed alongside those using the default selection in Section 6.6.

**TODO:** It's a bit awkward to reference the results of the default/optimized before they're properly presented. Maybe move the sections around? not sure...

Selection requirement	Selection value
Lepton kinematics	$p_T > 28$ GeV (leading lepton only)
Jet kinematics	$p_T > 90$ GeV (leading jet) $p_T > 45$ GeV (subleading jet)
Dilepton mass	$m_{ll} > 28$ GeV
Dijet mass	$m_{jj} > 520$ GeV
Lepton-jet centrality	$\zeta > -0.5$

Table 6.4: Updates to the  $W^\pm W^\pm jj$  event selection criteria after optimization. Cuts not listed remain unchanged from the default selection in Table 6.3.

## 6.6 Results

### 6.6.1 Event yields

After applying the full event selection, the analysis is broken down into four channels based off of the flavor of the signal leptons:  $\mu\mu$ ,  $ee$ ,  $\mu e$ , and  $e\mu$ . The full signal and background event yields are shown in Table 6.5 for each channel separately and combined using the default event selection. 3489 EWK  $W^\pm W^\pm jj$  events are expected compared to 9900 background events. The dominant sources of background are jets faking electrons followed by charge misidentification and diboson processes. Triboson events, QCD  $W^\pm W^\pm jj$ , and other non-prompt sources make up approximately 5% of the total background combined.

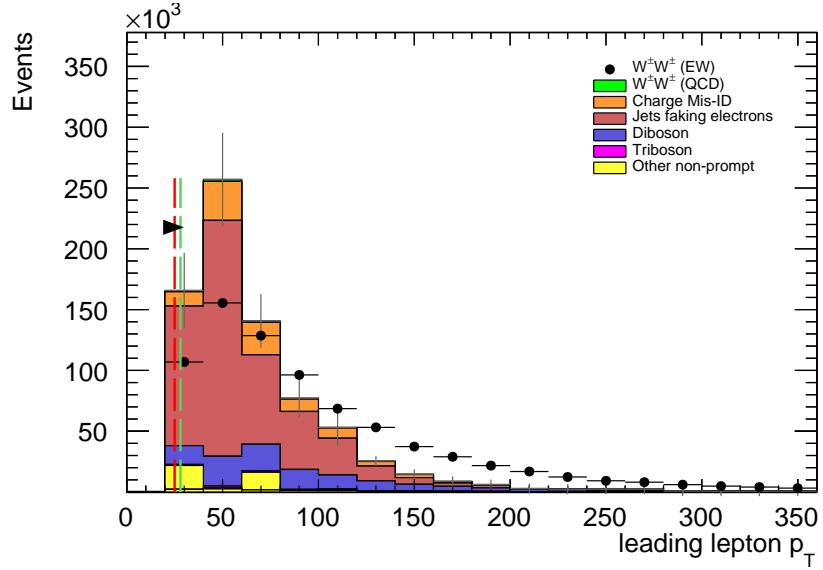

Figure 6.5: Leading lepton  $p_T$  distribution. The default and optimized cuts are represented by the red and green dashed lines, respectively. The  $W^\pm W^\pm jj$  EWK signal (black points) is normalized to the same area as the sum of the backgrounds (colored histogram). **TODO: Move to appendix or omit**

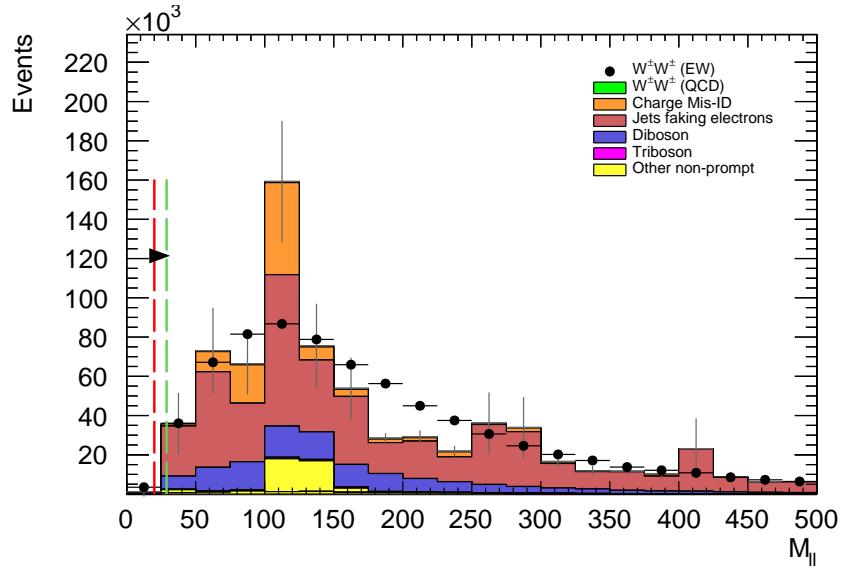

Figure 6.6: Dilepton invariant mass distribution. The default and optimized cuts are represented by the red and green dashed lines, respectively. Total Background	9900	750	6000	1900	1290
Signal $W^\pm W^\pm jj$ (EWK)	3489	1435	432	679	944

Table 6.5: Signal and background event yields using the default event selection for an integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . Events containing a fake or charge-flipped electron are removed from their respective sources and combined into a single entry each.

1818        The event yields for the optimized selection detailed in Section 6.5.3 are listed in Table 6.6. After  
 1819 optimization, 2958 signal events and just 2310 background events are expected. Diboson events are  
 1820 now the primary source of background, as the optimization greatly reduces the fake and charge  
 1821 misidentification backgrounds. As discussed earlier, the increase in the leading and subleading jet  
 1822  $p_T$  cuts as well as the loosening of the centrality cut are most responsible for the changes in the  
 1823 signal and background yields; distributions of these quantities using the default and the optimized  
 1824 event selections can be found in Figures 6.10, 6.11, and 6.12, respectively.

	All channels	$\mu\mu$	$ee$	$\mu e$	$e\mu$
$W^\pm W^\pm jj$ (QCD)	168.7	74.6	19.7	32.2	42.2
Charge Misidentification	200	0.0	11	30	160
Jets faking electrons	460	0.0	130	260	70
$WZ + ZZ$	1286	322	289	271	404
Tribosons	76	30.1	9.6	15.1	21.6
Other non-prompt	120	29	16.6	50	19
Total Background	2310	455	480	660	710
Signal $W^\pm W^\pm jj$ (EWK)	2958	1228	380	589	761

Table 6.6: Signal and background event yields using the optimized event selection for an integrated luminosity of  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . Events containing a fake or charge-flipped electron are removed from their respective sources and combined into a single entry each.

1825        It is important to note, however, that the MC sample used to estimate  $Z + \text{jets}$  events suffers from  
 1826 poor statistics which results in large per-event weights once scaled to  $\mathcal{L} = 3000 \text{ fb}^{-1}$ . This sample  
 1827 contributes heavily to the fake and charge misidentification backgrounds, and a handful of these  
 1828 events being cut out by the optimization contributes has a large effect on the dramatic reduction  
 1829 of these backgrounds. As a result, these particular optimized results are likely overly optimistic.  
 1830 However, given proper MC statistics, it is still expected that the optimization will outperform the

1831 default selection.

### 1832 6.6.2 Uncertainties

1833 TODO: Ask for details on how some of these uncertainties were calculated – specifically the fakes and  
 1834 charge mis-ID The uncertainties considered for the analysis are summarized in Table 6.7. Values for  
 1835 experimental systematics on the trigger efficiency, lepton and jet reconstruction, and flavor tagging  
 1836 are taken directly from the 13 TeV analysis [2]. The rate uncertainties for the background processes  
 1837 are halved from the 13 TeV values.

Source	Uncertainty (%)
$W^\pm W^\pm jj$ (EWK)	3
Luminosity	1
Trigger efficiency	0.5
Lepton reconstruction and identification	1.8
Jets	2.3
Flavor tagging	1.8
Jets faking electrons	20
Charge misidentification	25
$W^\pm W^\pm jj$ (QCD)	20
Top	15
Diboson	10
Triboson	15

Table 6.7: Summary of estimated experimental and rate uncertainties.

### 1838 6.6.3 Cross section measurement

1839 The cross section is calculated using the same method as in the 13 TeV analysis, detailed in Chap-  
 1840 ter 5. TODO: update from chapter reference to subsection reference (once it's written)... Once  
 1841 again, each of the four lepton flavor channels is further split by charge (i.e.  $\mu\mu \rightarrow \mu^+\mu^+ + \mu^-\mu^-$ ),  
 1842 as this increases the sensitivity of the analysis. Each channel's  $m_{jj}$  distribution is combined in a  
 1843 profile likelihood fit to extract the EWK  $W^\pm W^\pm jj$  production cross section. The expected cross  
 1844 section calculated using the default event selection is:

$$\sigma_{W^\pm W^\pm jj}^{\text{expected}} = 16.89 \pm 0.36 \text{ (stat)} \pm 0.53 \text{ (theory)} \pm 0.84 \text{ (syst)} \text{ fb} \quad (6.5)$$

1845 The expected cross section calculated using the optimized event selection is:

$$\sigma_{W^\pm W^\pm jj}^{\text{expected}} = 16.94 \pm 0.36 \text{ (stat)} \pm 0.53 \text{ (theory)} \pm 0.78 \text{ (syst)} \text{ fb} \quad (6.6)$$

1846 The optimized selection should not change the measured value of the cross section, and indeed both  
 1847 are consistent with within uncertainties. The systematic uncertainty is reduced by approximately 7%  
 1848 with the optimized selection. Projections of the total uncertainty on the cross section as a function  
 1849 of integrated luminosity made by [TODO: how was this made?](#) is shown in Figure 6.13. As the  
 1850 integrated luminosity increases past  $\mathcal{L} > 3000 \text{ fb}^{-1}$ , the statistical uncertainty reduces faster than  
 1851 the systematic uncertainties. However, the total uncertainty is expected to reduce by less than a  
 1852 percent with increased luminosity past the planned 3000  $\text{fb}^{-1}$ .

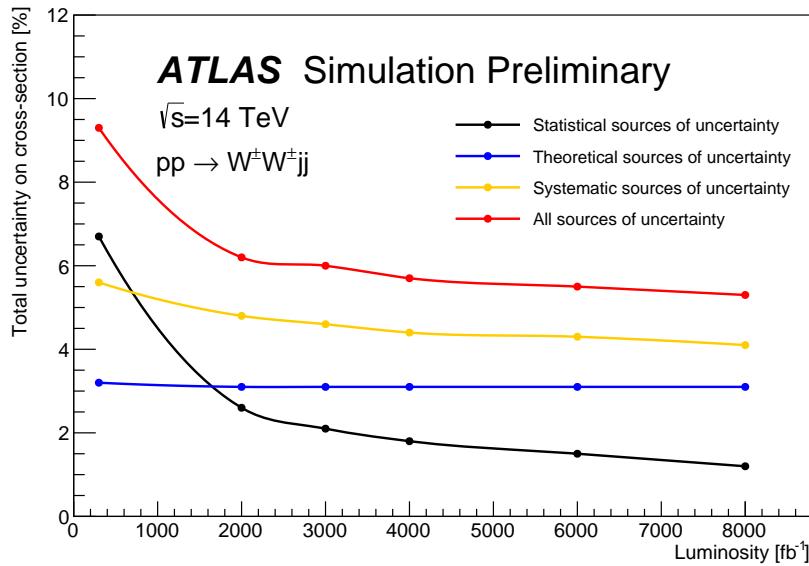

Figure 6.13: Projections of the statistical (black), theoretical (blue), systematic (yellow), and total (red) uncertainties on the measured cross section as a function of integrated luminosity using the optimized event selection.

#### 1853 6.6.4 Longitudinal scattering significance

1854 [TODO: get some details on how this was all done...](#) The longitudinal scattering significance is  
 1855 extracted from the  $|\Delta\phi_{jj}|$  distribution using a simultaneous binned likelihood fit. In order to increase  
 1856 sensitivity, the  $|\Delta\phi_{jj}|$  distribution was split into two bins in  $m_{jj}$ , and an additional cut on the  
 1857 pseudorapidity of the subleading lepton was applied ( $|\eta| < 2.5$ ) to reduce background from fake and  
 1858 charge misidentification. The  $|\Delta\phi_{jj}|$  distributions used in the fit are shown in Figure 6.14. Due to  
 1859 limited statistics, the four lepton flavor channels were not split by charge. The expected significance

<sup>1860</sup> of the  $W_L^\pm W_L^\pm jj$  process is  $1.8\sigma$  with a precision of 47% on the measurement. Projections of the  
<sup>1861</sup> expected significance as a function of integrated luminosity is shown in Figure 6.15.

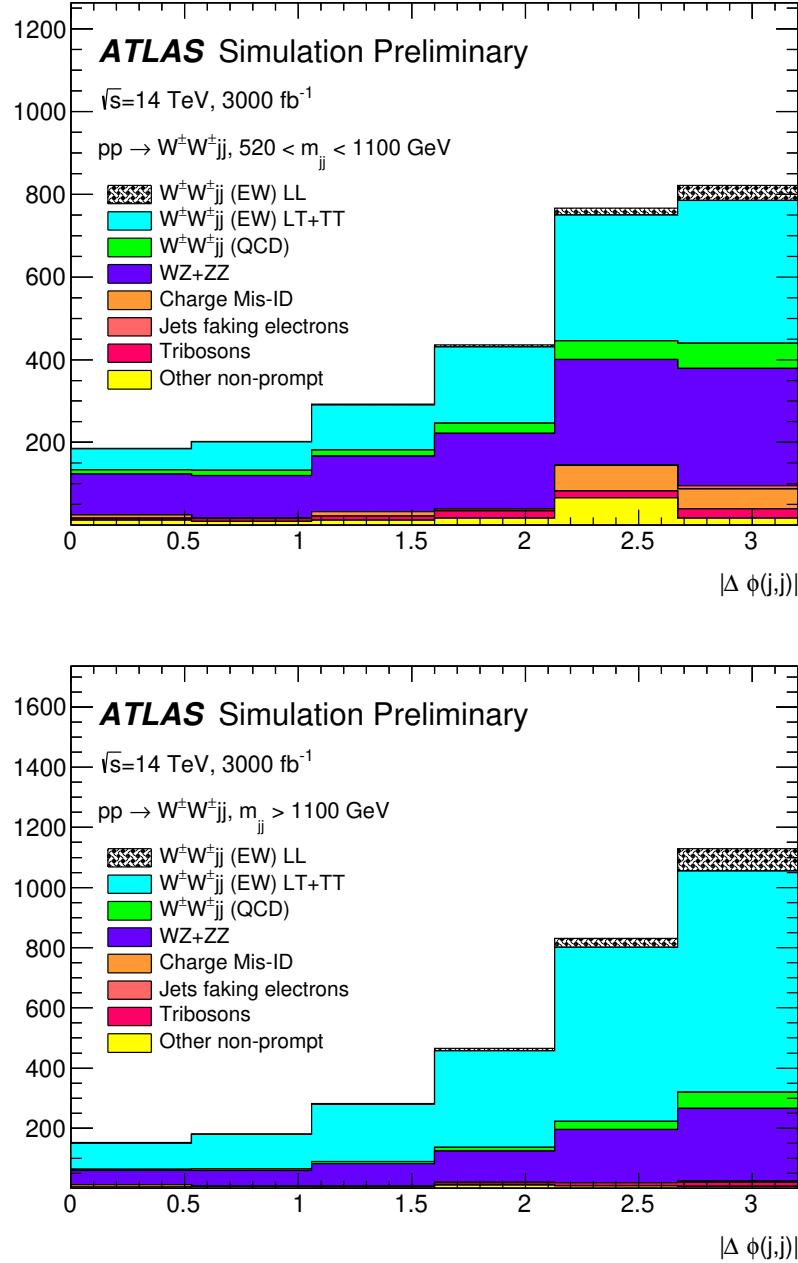

Figure 6.14: Dijet azimuthal separation ( $|\Delta\phi_{jj}|$ ) for the low  $m_{jj}$  region ( $520 < m_{jj} < 1100 \text{ GeV}$ , top) and the high  $m_{jj}$  region ( $m_{jj} > 1100 \text{ GeV}$ , bottom). The purely longitudinal (LL, gray) is plotted separately from the mixed and transverse (LT+TT, cyan) polarizations.

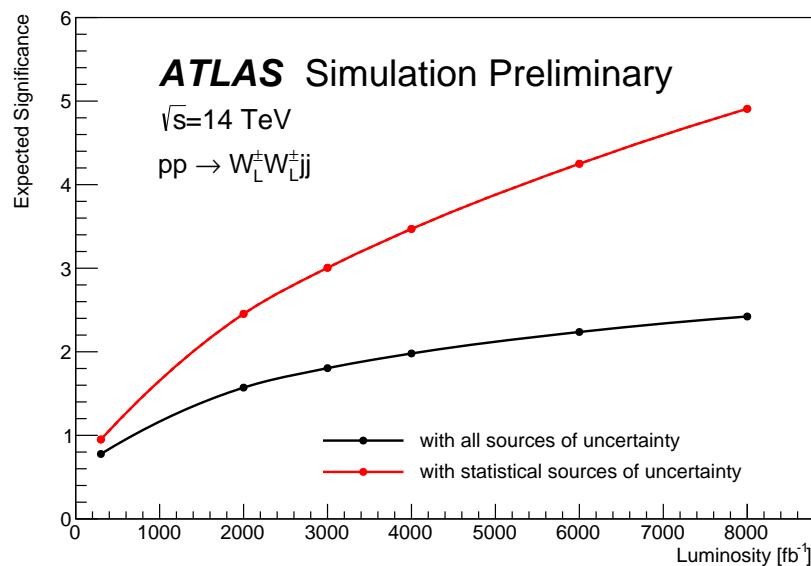

Figure 6.15: Projections of the expected longitudinal scattering significance as a function of integrated luminosity when considering all sources of uncertainties (black) or only statistical uncertainties (red).
